Goals and target group

[Online betrachten](#)

This document attempts to fill the following gaps in the accessibility publications:

- For Web documents, in W3C, there are several specific examples of how accessible pages must be designed (see, for example [How to Meet WCAG \(Quickref Reference\) \(w3.org\) \(External Link\)](#)). Corresponding documents are not available for software.
- Section 11 of EN 301 549 details the requirements concerning software. These requirements are of a general nature. There is no description of how UI elements must be specifically implemented in order to meet the requirements. For desktop software, there is no equivalent to the WAI-ARIA Authoring Practices ([WAI-ARIA Authoring Practices 1.2 \(w3.org\) \(External Link\)](#)).
- In the form of WCAG2ICT ([Guidance on Applying WCAG 2.0 to Non-Web Information and Communications Technologies \(WCAG2ICT\) \(w3.org\) \(External Link\)](#)) in 2013, W3C published a document describing the way in which the WCAG requirements can be applied to software and documents. This document is outdated, however, and does not contain the requirements of the current WCAG 2.1.

The document is primarily aimed at software developers.

Other roles in the field of software development for which the document may be helpful include

- Design (especially with regard to the requirements of [fonts](#) , [colors an contrasts](#) and the information in the “presentation” sections for each UI element),
- Editing for the text content of the software and Help,
- Accessibility test,
- Disabled people who use software (to familiarize themselves with common keyboard conventions, for example, refer to the “use of the keyboard” sections for each UI element).

Scope of validity

[Online betrachten](#)

Scope of validity

This document describes the accessibility requirements for Web and Desktop software as well as hybrid applications (which combine Web and Desktop technologies) which operate on the Microsoft Windows platform software and which have an [open functionality](#) . The requirements are primarily derived from EN 301 549 (version 3.2.1, sections 9 and 11).

This document does not initially apply to the following software:

- Software with [closed funktionalität](#) (Section 5.1 of EN 301 549),
- Software for two-way voice communication (section 6 of EN 301 549),
- Software with video functionality (section 7 of EN 301 549),
- Help authoring tools (section 11.8 of EN 301 549),
- Software with access to transposition or emergency services (section 13 of EN 301 549),
- Software that runs on platform software other than Microsoft Windows (such as Unix, Linux, Chrome OS, macOS, iOS, Android),
- [Assistive technology](#) ,
- Platform software,
- Apps for mobile devices (such as tablets or smartphones).

In addition, this document does not apply to:

- Hardware (section 8 of EN 301 549),
- Documents (section 10 of EN 301 549), even if the documents are interactive (e.g. spreadsheet with macros, PDF with form)

Many of the requirements described here can be transferred to software from other platforms.

Notes for the reader

[Online betrachten](#)

Layout of the document

The document is divided into the following sections:

- [Application-related requirements](#) , which apply to the whole of the software,
- [Element-spanning requirements](#) , which apply to all or several UI elements,
- [Text elements](#) ,
- [Grafical elements](#) ,
- [structural elements](#) (for the structuring of the dialog boxes in individual areas),
- [control elements](#) ,
- [Composite control elements](#) (complex control elements which consist of several simple control elements).

Each section contains several areas, “control elements”, for example, is divided into one section for each specific control element.

The individual sub-sections are divided into:

- Introduction:
 - Synonyms: Other names for the described UI element, which can also be used to locate the element in the index,
 - Reference to similar elements or related topics,
 - Description of the element or topic,
- Presentation (requirements concerning the visual presentation)
- Operation (operating requirements, especially with keyboard and pointing devices)
- Programming/interfaces (requests for information which are communicated to the [Accessibility API](#) .

The requirements are presented in table form:

[Klassifizierung der Anforderungen](#)) | Origin of the requirement (see

[Referenzen](#)) |

No.	Property	Description	Classification	Reference
-----	----------	-------------	----------------	-----------

No.	Property	Description	Classification	Reference
Unique requirement number	Topic-related classification of the requirement	Requirement to be met, supplemented with explanatory notes if necessary	Relevance of the requirement (see	

Note: The validity of the requirements is specified as follows:

- Web applications: “Web:”
- Desktop applications: “Desktop:”
- Hybrid applications: “Desktop:”
- Valid for all applications: Not applicable

Classification of the requirements

The requirements are classified as follows:

Classification	Meaning	Reference	Formulation
Must	<p>Legal requirement according to BITV 2.0</p> <p>Minimum requirements that must be met to achieve compliance with BITV 2.0</p>	<p>EN 301 549, Version 3.2.1 (External Link)</p> <p>Note: All the requirements of EN 301 549, sections 11.1 to 11.4, refer to the WCAG 2.1. The numbering of the corresponding requirements from EN 301 549 corresponds to the numbering in the WCAG 2.1.</p>	<ul style="list-style-type: none"> • Must • May not

Classification	Meaning	Reference	Formulation
<p>Should</p>	<p>Key requirements that should be met</p> <p>According to Section 3 (4) of BITV 2.0, efforts should be made to comply with the requirements for certain areas of application: “For central navigation and entry offers, as well as for offers that enable user interaction such as forms and the completion of authentication, identification and payment processes, efforts should be made to achieve the highest possible level of accessibility.”</p>	<ul style="list-style-type: none"> • WCAG (External Link) 2.1, AAA criteria • WCAG 2.1, A- and AA-criteria that are not a component of section 11 of EN 301 549 • WCAG 2.2 criteria (draft) • Other W3C specifications • Other ISO norms • Further standards of the DIN EN ISO 9241 series (suitability for use) with special relevance to accessibility 	<ul style="list-style-type: none"> • should • should not

Classification	Meaning	Reference	Formulation
Implementation recommendations, notes			<ul style="list-style-type: none"> • Note • Can • Recommended

The specific requirements concerning the use of the keyboard, i.e. which keys are to be used for which purpose, are classified as follows:

Classification	Meaning
Required	Minimum requirements If these requirements cannot be met, the alternate use of the keyboard should be documented.
Recommended	Recommended requirements The fulfillment of these requirements serves the purpose of easier and more efficient operations with the keyboard.

Note: The requirements regarding the use of the keyboard cannot be classified as “must” or “should”, as EN 301 549 only requires the possibility for the use of the keyboard, but does not define specific keys, as these depend on the respective platform, for example. The elementary guide also contains notes, recommendations and practical tips. These are not standardized. In the notes, recommendations and practical tips, however, “must”, “may not”, “should” and “should not” are used insofar as reference is made to a requirement.

Coverage of the requirements

The sections on general topics (“application-related requirements” and “element-spanning requirements”) address the dialog-related requirements of EN 301 549 (in particular, section 9 on Web and 11 on Software). The requirements are explained here in general (i.e. not in relation to specific UI elements) and in as much detail as possible (i.e. with possible special cases, exceptions, etc.).

In the sections on individual UI elements (text, graphic, structure, control elements), only the relevant requirements regarding the respective UI element are listed. This article describes what a general requirement means as regards a specific element. However, the requirements are not necessarily explained in detail; i.e. for special cases and exceptions, reference is made to the respective general section.

For example:

- In the section on the UI element [Checkbox](#) the requirement for the visual resizing of the check box is not addressed, because no check box-specific problems or requirements in relation to zooming exist. However, the requirements concerning the resizing can be found in the “resizing” section and also apply to check boxes.
- In the section on the UI element check box, the specific contrast requirements are described so as to further explain the extent to which the general contrast requirements from the “colors and contrasts” section apply to the check box. However, the special case of the disabled check box is not discussed here, because exceptions for disabled elements are described in the “colors and contrasts” section.

Coverage of the elements

The following elements are not described in this document due to their limited degree of relevance to software:

- Rich text editor,
- Video,
- Audio,
- Image map,
- Maps.

However, there is the intention to include these requirements and elements in a future version of the document.

Technology-specific features

Some programming languages or frameworks do not allow all the requirements to be met due to limitations to the respective technology. In this case, it should be checked as to whether another programming language or another framework can be used. Alternatively, the requirements should be met as sufficiently as possible. All deviations should be documented in the [help](#) and in the accessibility declaration.

This document does not address technology-specific features, but focuses on the expected behavior of the UI elements.

Application-related requirements

[Online betrachten](#)

Inhaltsverzeichnis

- [Conforming alternate version](#)

- [Error prevention and correction](#)
- [Help and support](#)
- [Resizing](#)
- [Accessibility API](#)
- [Authentication](#)
- [Animations](#)
- [Navigation sequence](#)
- [Changes of context](#)
- [Time limits](#)

Conforming alternate version

[Online betrachten](#)

If the application fails to meet all the accessibility requirements, a conforming alternate version can be made available. In this respect, however, the following requirements must be met:

- The conforming alternate version meets all the requirements, i.e. it is completely accessible. If several alternative versions are offered, at least one alternative version is fully conforming. Therefore, offering specific alternative versions for individual user groups which only meet the requirements of the respective group is not permitted unless there is no alternative version which fulfills all the requirements of all user groups.
- The conforming alternate version is equivalent in terms of all its content and functions to the version which is not accessible. This means that the alternative version may not contain outdated information. Insofar as the standard version is offered in different languages, the alternative version must also be offered in the languages.
- The conforming alternate version can be achieved in an accessible way. This means:
 - The function for changing to the conforming alternate version must be accessible.
 - The standard version may not contain any keyboard traps or flashing content. In addition, the standard version may not contain any moving, flashing, automatically updating or acoustic content that cannot be stopped (<https://www.w3.org/TR/WCAG21/#cc5>).
 - Alternatively, both the conforming and standard version can be achieved using an accessible screen (e.g. the login screen), or the conforming alternate version is the standard version.
- The purpose and achievement of the conforming alternate version is explained in the documentation.
- The Support Service can explain the purpose and achievement of the conforming alternate version (to comply with EN 301 549, section 12.2.2).

It is recommended that only one version of the application is offered at a time and that it is designed so that it is accessible.

Note 1: A typical use case for a conforming alternate version is when the standard version of the Web application does not meet the contrast requirements for content consisting of text or graphics due to the corporate design. In this case, the conforming alternate version can use a CSS marking that provides for sufficient contrast.

Note 2: For selected Web applications that are already largely accessible, an overlay tool may be able to generate a conforming alternate version that fully meets the above requirements. However, this is usually not the case, especially if the Web application has problems that cannot be found and fixed automatically. Therefore, an overlay tool cannot be used as a standard to provide a conforming alternate version ([Monitoring Center of the German Federal Government for the Accessibility of Information Technology - Publications - Joint Assessment of the Monitoring Centers of the Federal Government and Federal States for the Accessibility of Information Technology on the use of Overlay Tools \(bfit-bund.de\) \(External Link\)](#))

Note 3: For desktop applications, EN 301 549 does not make any statements about alternative versions. However, it may be assumed that the same requirements apply to desktop applications.

Application language and change of language

Resizing

[Online betrachten](#)

Synonyme: Scaling, adjusting the font size, zoom

See also: [font](#) , [text](#)

The following requirements should ensure that the font size can be adjusted to the user preferences without assistive technology.

Presentation

No.	Property	Description	Classification	Reference
29	Resizing	<p>It must be possible to resize the text of the application by up to 200% without the use of assistive technology. The resizing may not lead to a loss of content or functionality.</p> <p>Note 1: To do this in desktop applications, the application can offer its own zoom function or support the font size adjustment of the operating system (Settings > System > Display > Scale and layout: advanced scaling settings).</p> <p>Note 2: For Web applications, the zoom function of the browser should be supported.</p> <p>Note 3: For superior perceptibility, it should also be possible to resize non-text content.</p>	Muss	EN 301 549: 9.1.4.4, 11.1.4.4.1

No.	Property	Description	Classification	Reference
30	Resizing	<p>In the case of a screen size with a width of 320 px and a height of 256 px, no loss of content or function may occur. It should only be necessary to scroll content in either the vertical or horizontal direction, and not in both directions. Two-dimensional scrolling is only permitted with elements that are invariably two-dimensional (such as graphics, maps, videos or tables)</p> <p>Note 1: This requirement should ensure that the content can be resized by up to 400%.</p> <p>Note 2: When using a zoom ratio of 400%, all the content must be scaled accordingly. This does not apply to content that is already sufficiently large, such as headings. It must be possible to resize these by at least 200%.</p> <p>Note 3: If text is placed within two-dimensional content, such as tables, a single block of text (in a table cell, for example) must be readable without the need for two-dimensional scrolling.</p>	Must	EN 301 549: 9.1.4.10, 11.1.4.10

Accessibility API

[Online betrachten](#)

Synonyms: Accessibility interface, interoperability with assistive technology, compatibility with assistive technology, platform support for accessibility services for assistive technology, programming interface for assistive technology

See also: [Element status](#) , [changes of context](#) , [contrast adjustment](#)

Assistive technology such as screen readers, screen magnifiers, Windows Contrast Adjustment and voice input software do not generally interact directly with the software or the browser, but using an interface for the accessibility which is made available by the operating system, for example: the Accessibility API (Application Programming Interface). The software and/or browser sends all the relevant information to the Accessibility API in standardized form, and the assistive technology accesses the information which is made available in the Accessibility API. However, the assistive technology only uses the information from the Accessibility API, which is relevant based on the needs of the user. If applications are operated using assistive technology, to a certain extent the operation does not take place directly, but is also conveyed using the Accessibility API.

The best-known Accessibility APIs on Microsoft Windows are:

- IAccessible2,
- MSAA (Microsoft Active Accessibility, Standard 1997-2005),
- UIA (Microsoft UI Automation, Standard seit 2005).

Windows applications should use the current Accessibility API UIA.

Software which does not use the Accessibility API of the operating system can implement its own interfaces for the communication of information to the assistive technology. In this context, Java applications use the Java Accessibility API (JAAPI).

The following information, for example, is communicated by the software and/or the browser to the Accessibility API and read out by the assistive technology if required:

- Role of an object (e.g. heading, check box, table cell),
- Status of an object (e.g. focused, focusable, disabled, open),
- Labeling of an object,
- Description of an object,
- Value of an object (e.g. for form fields),
- Possible values (e.g. maximum and minimum values in the case of specific form fields),
- Position in the object hierarchy (e.g. parent and child objects, amount of sibling objects, position relative to sibling objects),
- Spatial size and location in terms of the current screen area,

- Events (e.g. change of object properties).

Please note:

- Most programming languages which are usable for software development purposes support an Accessibility API. This applies to browsers as well.
- In this respect, the Accessibility API is usually supported automatically as long as the default elements of the programming language or markup language (e.g. HTML) are used. For example, if the language provides input fields as a control element, then the role, value, status, position in the object hierarchy, size, and location of the input field will be communicated correctly to the Accessibility API. In most cases, it is necessary for the visible label to be linked to the input field correctly so that it is also communicated to the API as the label of the input field.
- This applies in the same way to the standard characteristics of the programming language or markup language, which are communicated to the Accessibility API automatically. If an input field is provided with the “disabled” characteristic for example, the “disabled” and “not keyboard focusable” characteristics are communicated to the API automatically. 05.15.2023 Page 20 of 317
- Depending on the programming language or markup language used, it may be the case that certain characteristics of the object that are to be communicated to the Accessibility API must be explicitly specified (i.e. in text form), as otherwise they cannot be communicated.
- Unless a default element of the programming language or markup language is used, the developers are required to ensure that all the relevant object information is communicated to the Accessibility API correctly. If the language does not provide a possibility to explicitly define this information, only default elements should be used.
- If a programming language does not support an Accessibility API or it does not offer an alternative form of access to the required information through the various assistive technology, it should not be used, or the software must then meet the requirements detailed in Section 5.1 (closed functionality) of EN 301 549.

Programming/interfaces

[Element status](#) and

[Operability status](#)). | Must | EN 301 549:

9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!35 | Value | The value of the elements must be communicated to the Accessibility API. In the case of elements that have a defined range of values, the minimum and maximum values must also be communicated to the Accessibility API. | Must | EN 301 549:

9.4.1.2, 11.4.1.2, 11.5.2.7 | | @!36 | Orientation | If the orientation of the element has an influence on the operation, the orientation must be communicated to the Accessibility API.

[keyboard shortcut](#) or a visually perceptible shortcut key, these must be communicated to the Accessibility API. | Must | EN 301 549:

9.1.3.1, 11.1.3.1 | | @!39 | Desktop: Element hierarchy | The parent / child relationships of the elements must be communicated to the Accessibility API.

Note: This can be achieved with the following methods:

Note: Different or additional operating options should be documented in the application and the Help option.

Note 1: This applies, for example, to the enabling of elements, value and status changes, as well as changes of position for the focus and text cursor.

Note 2: This does not apply to security-related applications for intelligence or military services, or to encryption software for the purposes of national security.

[Status messages](#) must be marked so that they are output by the assistive technology without receiving the focus.

| Must | EN 301 549:

9.4.1.3, 11.4.1.3.1 | | @!46 | Desktop: Position | The spatial size and position of the elements must be communicated to the Accessibility API (see

Practical tip: Accessibility API with desktop applications

The [default elements](#) of the platform software or the framework used typically communicate the correct information to the Accessibility API automatically. They should therefore be used with preference.

Example 1:

- The following figure shows the “Save as” dialog of the “Windows Fax and Scan” application.
- A complete list of the information which is communicated to the Accessibility API for the “file name” input field which is located in this dialog (read out with Accessibility Insights for Windows) is also shown.
- In addition, the text-to-speech output of the screen reader JAWS is displayed during the focusing of the “file name” input field. For the acoustic output, JAWS only uses the Accessibility API information which is relevant in the current context (e.g. label, role, value, keyboard shortcuts), partially translates this information into the application language (e.g. the “Edit(50004)” role into “input field”), and supplements this information with its own operating instruction (“add text”), which is derived from the communicated role.

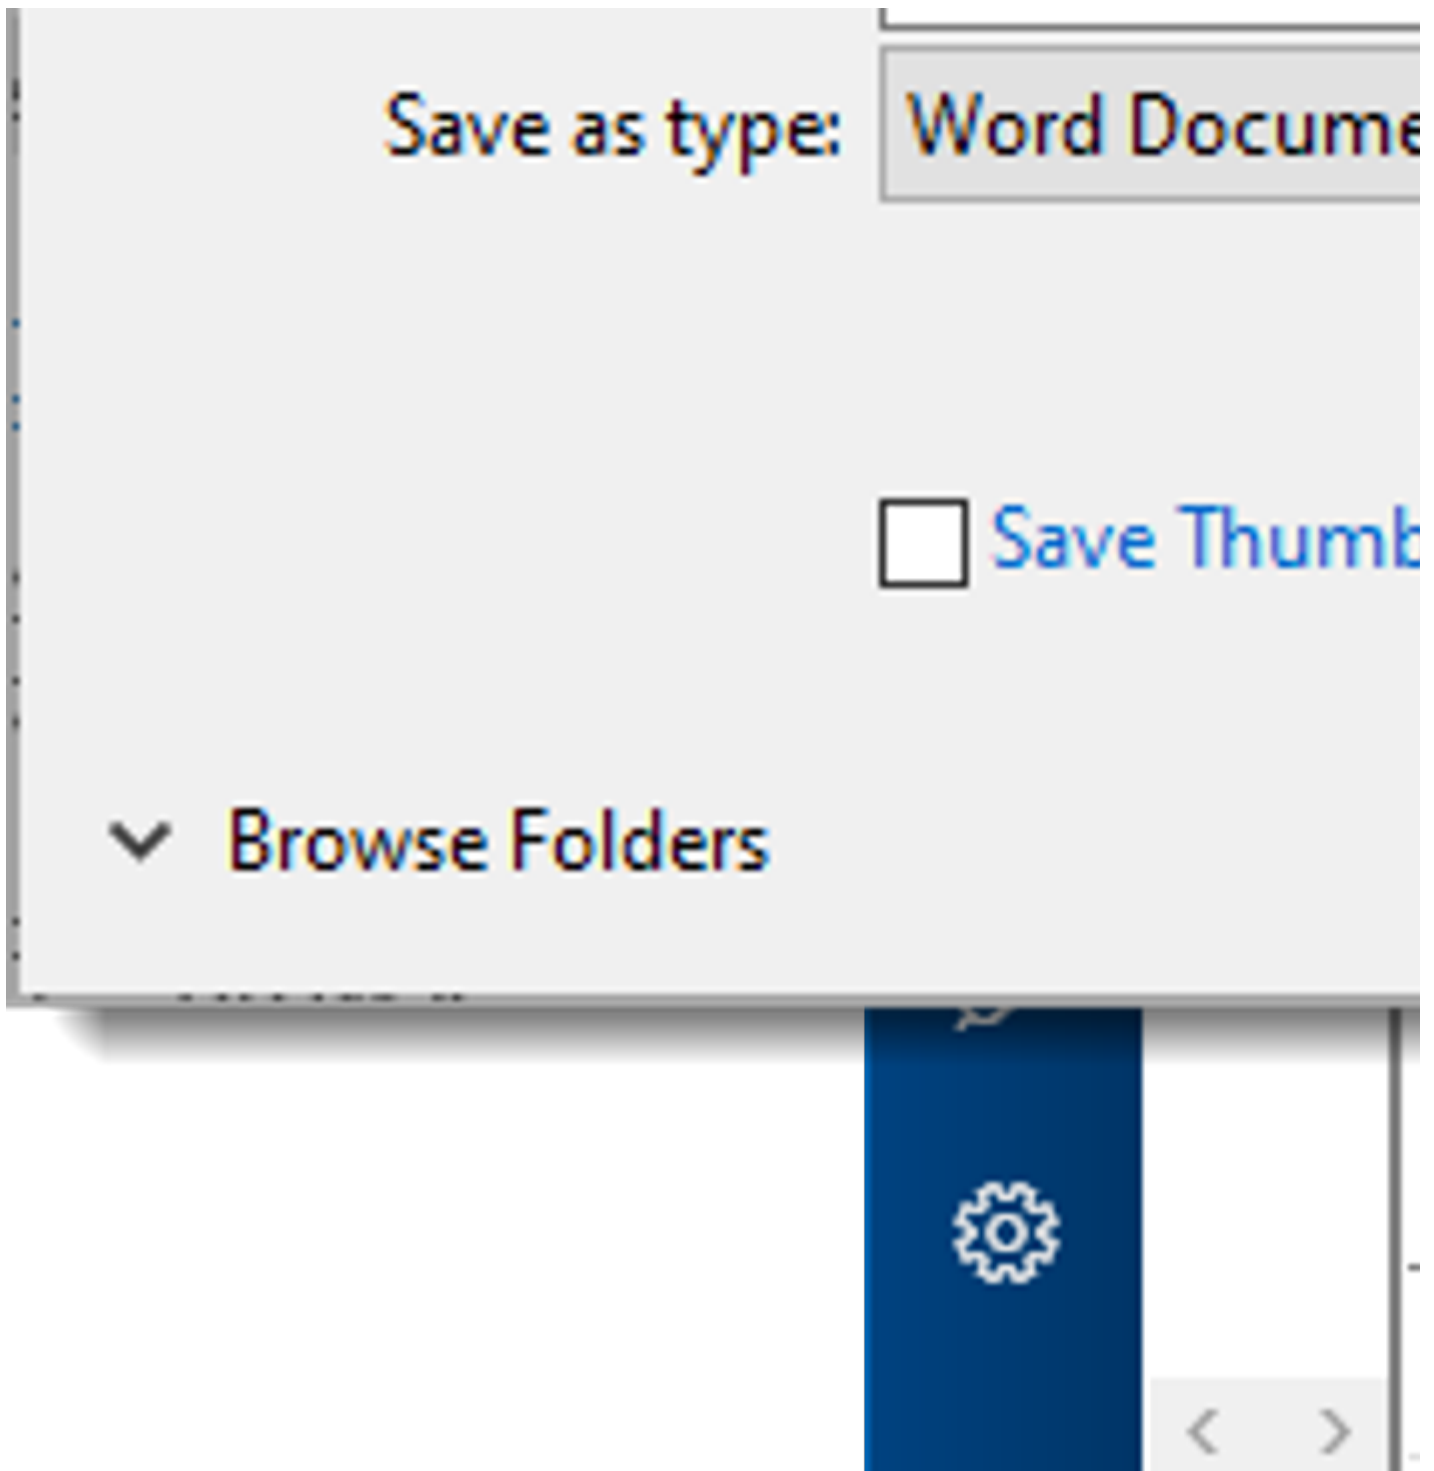

Figure 1: Information of the Accessibility API and its use by the screen reader JAWS

If [custom elements](#) are used, attention should be paid to the following in particular:

- the communicated role corresponds to the visual presentation and operation (in particular the use of the keyboard),
- the value and status should be communicated to the Accessibility API,
- the [label](#) is communicated to the Accessibility API as the Accessible Name,
- if available, the [keyboard shortcuts](#) , [description](#)) (as Accessible Description) and labels of the groups are also communicated to the Accessibility API,
- Updates concerning the value, status, label, etc. are communicated to the Accessibility API (note: the role of an element should not be changed).

If a custom element is implemented, it is often recommended that a related default element is used and customized accordingly, as it is then possible to use the basic functionality of the default element.

The corresponding characteristics of the Accessibility API should be used for the communication of the information. If there is no corresponding characteristic for sending the information in the Accessibility API or if the framework used does not support this characteristic, the information must be communicated in text form (i. e., as part of the Accessible Name or the Accessible Description).

For example: Disabled elements

- Disabled elements can usually be marked as disabled with an attribute. In the Accessibility API UIA, this corresponds to the `IsEnabled:false` characteristic. Assistive technology detects that the element is disabled due to this characteristic.
- If a programmatic marking as disabled is not possible, alternatively, the following options can be applied:
 - The element is removed.
 - The element is not designed as focusable (as long as it does not send any information and is not located within a range which can be read with the [virtual cursor](#)).
 - The element is named as “disabled” in the Accessible Name or Accessible Description.

For example: Button with value

- A button can have no value by default. Using Windows, however, it is possible to create a “button with value” custom element, which is based on the default button element. The value is then communicated to the Accessibility API UIA as the value of the Value characteristic.
- In HTML and ARIA, it is not possible to assign a value to a button. If the “button with value” is to be used in a hybrid application which is based on Web technologies, the value must be communicated in text form as part of the Accessible Name or the Accessible Description.

The communication of information about the corresponding characteristics of the Accessibility API is always to be preferred over the communication of such information in text form (as part of Accessible Name or the Accessible Description) for the following reasons:

- the assistive technology is able to output the characteristics which are communicated using the API in a way which is defined by the application or by the users,
- the assistive technology is able to translate the characteristics communicated using the API into the correct language,
- the assistive technology is able to output operating instructions or to offer operating modalities according to the characteristics which are communicated using the API,
- the assistive technology is able to offer a specific form of presentation based on the characteristics communicated using the API (e.g. a specific color when using [contrast adjustment](#)),),
- the assistive technology is able to output the characteristics (such as role, status, value) in a specific sequence, which ensures that relevant information is output first and that users are able to identify which information belongs to which type of characteristic,

- if required, users can configure their assistive technology so that they do not wish to receive outputs for certain characteristics.

None of this is possible if the information is only communicated in text form.

Example 2: The following figure shows three buttons with the label “Submit”, “Check” and “Delete”.

- The “Submit” button is visually identifiable as operable (black text color).
- The “Check” button is visually identifiable as disabled (gray font color). The button is programmatically marked as disabled. This implementation is to be preferred for disabled buttons.
- The “Delete” button is also visually identifiable as disabled (gray font color). The button is not programmatically marked as disabled, but only has one tooltip with the word “disabled”. This implementation may only be selected for disabled buttons if no programmatic marking as disabled is possible in the technology which is used.

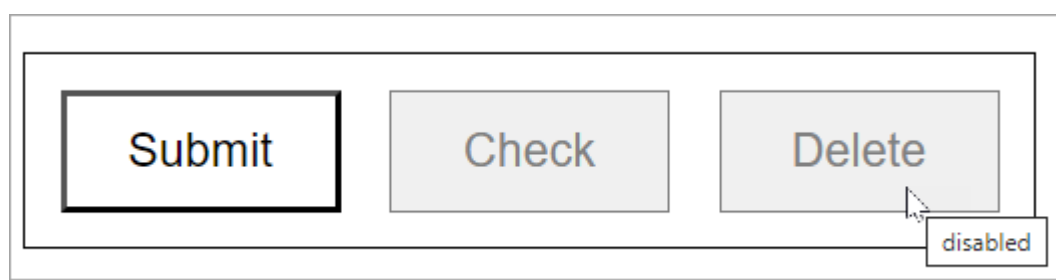

Figure 2: Three buttons, two of which are shown as disabled.

The following figure shows the same buttons from the previous figure, but when using Windows Contrast Adjustment (Contrast no. 1).

- The “Submit” button is correctly visually identifiable as operable (white text color).
- The “Check” button is correctly visually identifiable as disabled (green font color).
- The “Delete” button is displayed as operable (white text color), although it is disabled. The reason for the incorrect presentation is that it was not programmatically marked as disabled, but only as disabled in terms of its color. The color information is lost when using Windows Contrast Adjustment, however, so that a different visual presentation must be used here for the identification of the “disabled” status (e.g. a strike-through).

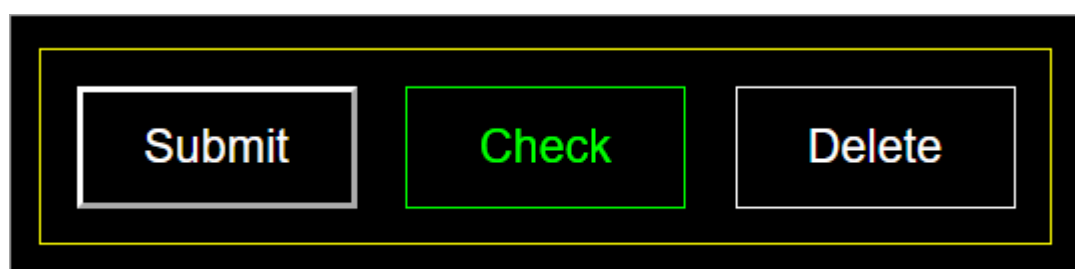

Figure 3: The three buttons from the previous figure when using Windows Contrast Adjustment.

The following figure shows the acoustic screen reader output of the three buttons from the previous figure (with the example of the JAWS element overview).

- The “Submit” button is correctly output as operable (“button” role).

- The “Check” button is correctly output as disabled (“not available” status).
- The “Delete” button is incorrectly output as operable (“button” role), as the “disabled” status is only communicated by tooltip, and the tooltip content is only output by the screen reader with certain navigation methods.

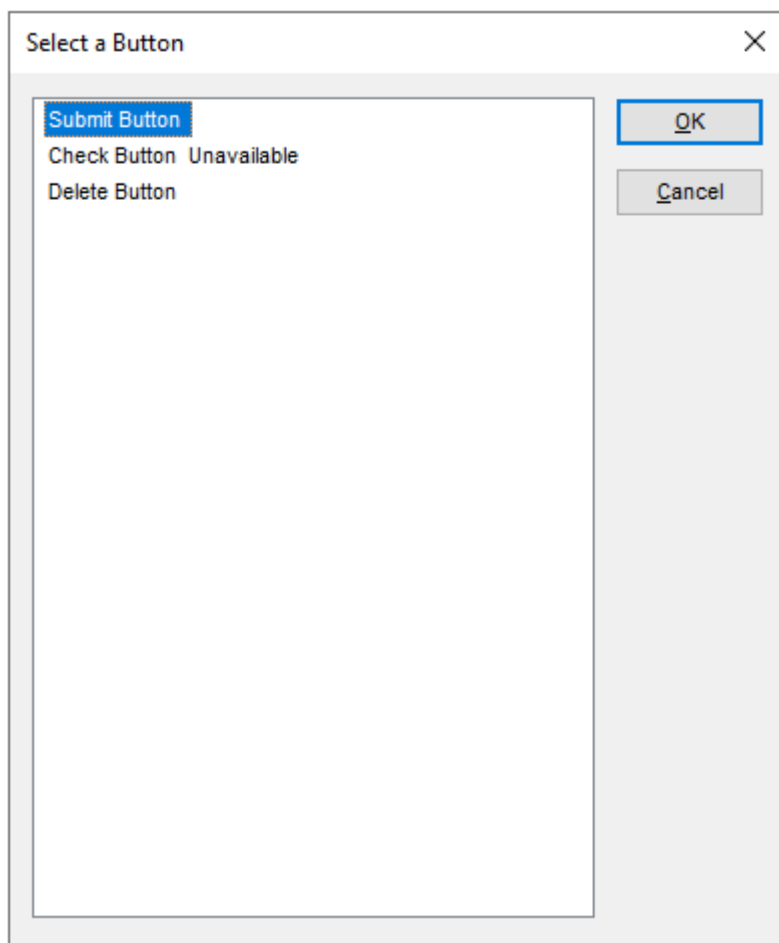

Figure 4: Screen reader output of the three buttons from the previous figure.

In the three following figures, the output of the three buttons from the preceding figures is shown on the Braille line (with the example of JAWS).

- The “Submit” button is correctly output as operable (“button” role) which is shown with the abbreviation “str”).
- The “Check” button is correctly output as disabled (“not available” status, which is shown with the abbreviation “xx”).
- The “Delete” button is shown as disabled (“disabled” description), but the output is not in the abbreviated form, not at the expected position, and is not translated into the language of the user.

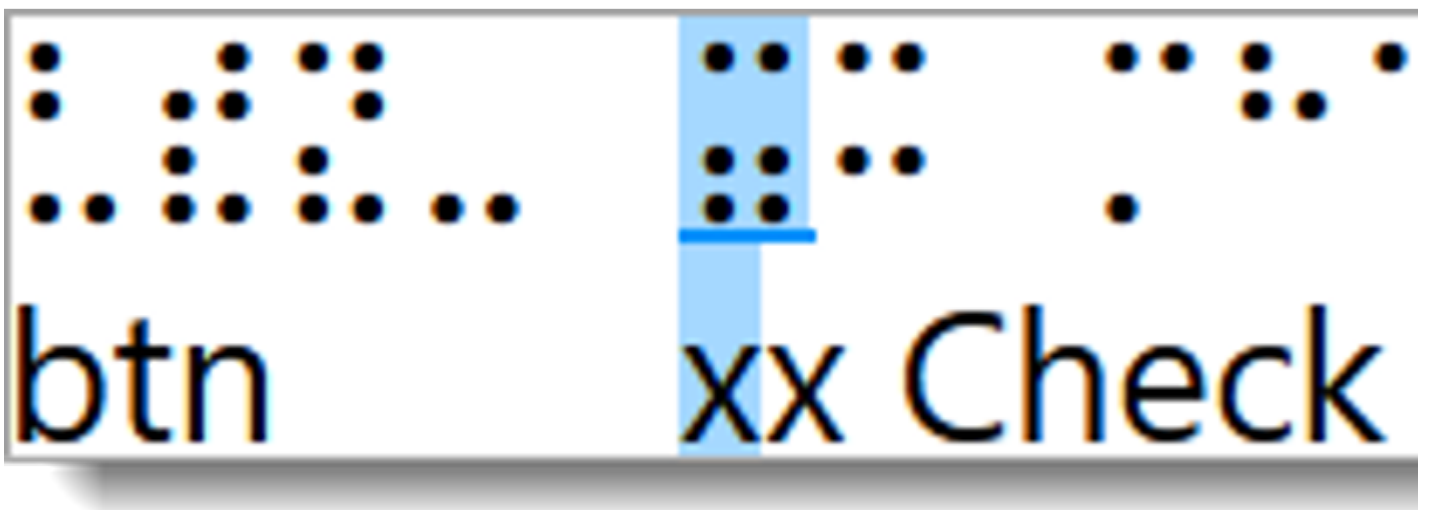

Figure 5: Braille output of the three buttons from the previous figures.

Authentication

[Online betrachten](#)

Synonyme: Sign in, sign out, login, logout

See also: [Changes of context](#) , [time limits](#) , [password input field](#)

The authentication encompasses the processes of signing in and out of an application or within an application. Logging in may be required to be able to use an application or certain parts of the application.

Note: Requirements regarding the authentication control elements (such as input fields, password input fields and buttons) are described for the respective element.

Presentation and operation

No.	Property	Description	Classification	Reference
48	Captcha	<p>If a Captcha is used during the authentication, appropriate Captchas with at least two different sensory systems must be offered for different disabilities.</p> <p>Note 1: For hearing-impaired people, a visual Captcha can be offered, and for blind people, an audio Captcha can be offered.</p> <p>Note 2: The use of Captchas which require users to solve a task should be avoided as far as possible.</p> <p>Note 3: If a Captcha cannot be dispensed with, a non-sensory Captcha (such as one with a general knowledge question or a math task) should also be offered.</p>	Must	EN 301 549: 9.1.1.1, 11.1.1.1

56	Status	<p>If the technology used is able identify the input purpose of form fields, the purpose of the form fields must be marked for the data of the respective users (such as the name, email address, password) according to Input Purposes for User Interface Components - Web Content Accessibility Guidelines (WCAG) 2.1 (w3.org) (External Link)</p> <p>Note: This does not mean the role (e.g. "input field") or the specific label (e.g. "user name"), but a defined input purpose (e.g. "first name", "user name", "new password" or "current password").</p>	Must	EN 301 549: 9.1.3.5, 11.1.3.5.1

Animations

[Online betrachten](#)

Synonyms: Sparkling, flashing, updates, flash

See also [Time limits](#) , [carousel](#) , Video, [progress bar](#)

Animations are:

- automatic visual changes or
- unexpected visual changes when using the application.

Examples of automatic visual changes:

- moving text,
- automatically started video,
- automatically scrolling content,
- sparkling or flashing content,
- content that is automatically updated after a certain time.

Examples of unexpected visual changes when using the application are:

- content is additionally animated when scrolling in the screen,
- content is scrolled through at different speeds when scrolling in the screen,
- manually started video contains flashing content,
- flashing error message which is shown after sending a form,
- when viewing content, the content is not displayed immediately, but shown in animated form (e.g. scaled, shifted, rotated or changed in terms of its transparency).

Presentation

No.	Property	Description	Classification	Reference
57	Status	Content which flashes for more than 3 times per second and exceeds a certain flash threshold (siehe General flash and red flash thresholds - Web Content Accessibility Guidelines (WCAG) 2.1 (w3.org) (External Link) ___), must be avoided.	Must	EN 301 549: 9.2.3.1, 11.2.3.1

Navigation sequence

[Online betrachten](#)

Synonyms: Tab sequence, focus order

See also: [Use of the keyboard](#) , [Changes of context](#) , [Time limits](#)

The navigation sequence decides the sequence in which the elements and areas to be focused with the keyboard receive the focus. Typically, this applies to the following navigation methods:

- Navigating between the elements with the tab key,
- Navigating within the elements with the arrow keys,
- Navigating between areas (e.g. with the F6 key),
- Quick navigation (e.g. with PAGE UP, END).

Operation

[modal dialog](#) this receives the focus,

- the buttons for submitting a form are located at the end of the form

Note: This relates to, for example, radio button groups, selection lists, tabs, menus, toolbars..

For example: After deleting an element, the focus should be positioned on the previous or next element.

Note: The rest of the application can only be focused and operated when the modal dialog is closed.

Note 1: For German language applications, this usually means that the navigation should correspond to the reading sequence, and should take place from the top left to the bottom right.

Note 2: The navigation sequence should match in both navigation directions (forward and backward).

Note 3: It may be necessary for the visual sequence to be adjusted to meet this requirement.

[Practical tip: efficient keyboard navigation](#)). | Must | EN 301 549: 9.2.4.1 | | @!70 | Change of context | No loss of focus may occur during the keyboard navigation. | Must | EN 301 549: 9.3.2.1, 11.3.2.1 | | @!71 | Change of context | Form elements may not be subject to an unexpected loss of focus when changing their value (see

Practical tip: navigation sequence in Web applications

HTML

The correct navigation sequence should be controlled by the order of the elements in the source code. The `tabindex=0` attribute should not be used. The autofocus attribute should only be used with caution, as the contents before the automatically focused element are only perceptible with difficulty for visually impaired or blind people. There are applications in which autofocus can be put to good use, however, e.g. on a login page for the focusing of the first input field. Further information: [6.6.3 The tabindex attribute - HTML Standard \(whatwg.org\)](#), [6.6.7 The autofocus attribute - HTML Standard \(whatwg.org\)](#)

ARIA

The correct navigation sequence should be controlled by the order of the elements in the source code. The `tabindex=0` attribute must be used for control elements that would not otherwise receive the keyboard focus. Elements that should be focusable by JavaScript but are not automatically in the TAB circuit are marked with `tabindex=-1`. This applies, for example, to [buttons](#) in [toolbars](#), Einträge in [selection lists](#) oder [radio buttons](#) within a group of radio buttons. In these cases, just one button, one list entry and/or one radio button is marked with `tabindex=0` and all others are marked with `tabindex=-1`. Further information: [Developing a Keyboard Interface | APG | WAI | W3C](#)

Practical tip: efficient navigation in applications

If the current application window contains several focusable elements, users who depend on the use of a keyboard cannot navigate through the window efficiently because they have to use the TAB key to navigate through these elements. To allow for an efficient form of keyboard navigation, it is recommended that one or more of the following methods are implemented and documented in the [Hilfe](#) option:

- Area navigation (e.g. with F6),
- Skip links at the start of the window and/or before areas with several navigation steps,
- [keyboard shortcuts](#) for frequently required functions and/or control elements,
- Designing areas with several navigation steps so that they can be shown and hidden (e.g. [Menu](#) with sub-menus, [tabs](#), [accordion](#)),
- Outsourcing of contents with several navigation steps to secondary screens (e.g. in dialog windows which can be opened separately),
- Use of grouping elements that are navigated within using the arrow keys instead of the TAB key (e.g. [toolbar](#), [menu](#)),
- with applications that do not support the [virtuellen Cursor](#): Mode in which control elements receive the focus only.

Changes of context

[Online betrachten](#)

Synonyms: Updates, change of context

See also: [Animations](#) , [time limits](#) , [navigation sequence](#) , [modal dialog](#)

Changes of context are:

- Changing to another program,
- Changing of the view port (e.g. switching to another application window),
- Changes to the keyboard focus,
- Changing the content that changes the meaning of the page.

Changes of context expected and required during operation include:

- Enabling a link: Opening a new screen,
- Enabling a Help link: Open Help, possibly in another application (e.g. in a browser or PDF reader),
- Enabling an internal page link: Scrolling to the linked location and changing the keyboard focus,
- Enabling a Submit button: Opening a new screen,
- Enabling a Delete button: Removing the element to be deleted, possibly changing the keyboard focus if necessary (as the delete button has been disabled or removed),
- Enabling the Logout button: Logout from the application,
- Enabling a Menu button: Opening the menu and focusing of the first menu item,
- Enabling a button to open a modal dialog: Opening the dialog and focusing of the first element in the dialog,
- Page scrolling: change of the visible area,
- Navigation with the keyboard (e.g. with the tab key): Change of the keyboard focus, possible change of the visible area (if the focused element is not situated in the visible area),
- Navigating through a radio button group in which there are associated form fields behind each radio button which can only be operated depending on the radio button: The form elements are enabled when the radio button is selected, the other form elements are disabled.
- Navigation through a group of tab panels: The corresponding tab is shown (alternatively, only after the enabling of the tab panel).

Examples of unexpected changes of context which must be avoided or announced:

- Enabling of a check box within a form: Showing additional form fields that are visually located in the navigation sequence before the check box,

- Text input in an input field: Deleting of entries already made in other fields because the entries in this field and the other fields are mutually exclusive,
- Text input in an input field: After reaching the maximum number of characters, the focus is placed in the following input field,

Examples of unexpected changes of context which have to be avoided or announced:

- Enabling a link: Opening a new screen in another application,
- Enabling of a tab panel: The displayed tab or an element in it receives the focus.

Examples of unexpected changes of context which must be avoided:

- Navigation through a group of radio buttons: Opening a new screen,
- Navigation through a table: Opening a modal dialog,
- Fully filled out form: Submitting the form,
- Focusing of a Submit button: Submitting the form,
- Focusing of the Delete button: Removing the element to be deleted.

Time limits

[Online betrachten](#)

Synonyme: Timeout, Time limit

See also: [Animations](#) , [changes of context](#) , [authentication](#) , [carousel](#)

Time limits are specified time constraints in which to view content, operate elements or complete tasks. Time limits may occur, for example, if

- an automatic logout occurs after a certain period of inactivity,
- a PIN required for authentication is only valid for a certain time,
- messages are hidden after a certain time,
- content is updated automatically (e.g. in a carousel),
- scrolling is displayed.

Keyboard shortcuts and shortcut keys

[Online betrachten](#)

Synonyms for keyboard shortcuts: Key combination, keyboard combination, keyboard command, keyboard equivalents, key sequence, access key, hot key, shortcut

Synonyms for shortcut keys: Mnemonic, acceleration key, shortcut key, menu accelerator

Keyboard shortcuts are keys or combinations of keys with which functions can be initialized or elements can be focused from within the application. The keyboard shortcuts can be initialized regardless of the current focus position. Keyboard shortcuts often consist of a combination of a printable character (letter, number, special character) with one or more modifier keys (e.g. CTRL or ALT). Keyboard shortcuts must be unique.

Shortcut keys are keys that can only be used within an element for the purpose of efficient navigation. They are usually used in menus. The shortcut key is usually the first letter of the corresponding element (e.g. menu item). Shortcut keys do not have to be unique: If, for example, different entries within a menu have the same shortcut key, the entries can be focused one after the other by pressing the key. Shortcut keys are used without modifier keys.

Practical tip: keyboard shortcuts and shortcut keys

Platform-specific keyboard shortcuts

The keyboard shortcuts of the platform (of the Windows operating system, for example) should not be overridden or disabled in your application. i.e. the keyboard shortcuts of the platform should also work in the application (e. g. CTRL+X and CTRL+V to cut and paste text).

Keyboard shortcuts of assistive technology

The assistive technology uses several keyboard shortcuts. These keyboard shortcuts should not be used in the application, as otherwise the assistive technology or the application won't work with these keyboard shortcuts.

The screen readers use the INSERT key as a modifier key for several of their keyboard shortcuts, for example. Therefore, the INSERT key should not be used as a modifier key for the keyboard shortcuts of the application.

As assistive technology also uses additional modifier keys and keyboard shortcuts without modifier keys, it should be possible to redefine or disable application-specific keyboard shortcuts.

Configuring keyboard shortcuts

Regardless of the assistive technology which is used, keyboard shortcuts are important for people who depend on the use of the keyboard. The application should therefore make it possible to define special keyboard shortcuts for all functions, even if they are not provided with any keyboard shortcuts by default. Where this is possible, the Help option should make reference to it.

Documentation of the keyboard shortcuts and shortcut keys

The keyboard shortcuts should be explicitly documented in the application, i.e. in text form at the respective element (permanently visible or in a tooltip), e.g. "Print (CTRL+D)".

The shortcut keys should be implicitly documented in the application, by underlining the letter for example, such as "Print".

The shortcut keys within selection lists and drop-down lists are not generally documented – there, the first letter of the respective list entry acts as the shortcut key.

In the Help option, the keyboard shortcuts should be documented as follows:

- Documentation of the respective keyboard shortcuts within the topic-specific sections (description of a screen, function, elements etc.) as well as
- Documentation of all keyboard shortcuts on a separate page with instructions for the use of the keyboard.

Use of the pointing device

[Online betrachten](#)

Synonyms: Use of the mouse, use of the touch pad, use of the pen, pointing device operation, pointer operation

See also: [Use of the keyboard](#)

The use of the pointing device encompasses all the operational modalities with a pointing device, e.g.

- Mouse,
- Graphics tablet,
- Touch pad,
- Touch display,
- Track point,
- Track ball,
- Joystick,
- Pen.

113	Desktop: Consistency	Control elements that have the same functionality should be designed consistently within the application.	Should	WCAG 2.1: 3.2.4 (AA)

Operation

From the perspective of accessibility, there is no compulsory requirement for an application to be operable with a pointing device. All that is required is the operation with the keyboard. However, if an application can be operated with a pointing device, specific requirements must be met.

[decorative non-text content..](#)

Note 2: The automatically-shown content can be hidden, e.g., with ESC or clicking on the triggering element, as long as no other actions are triggered.

- the content was deliberately closed (e.g. with ESC) or
- the content is no longer valid (e.g. an error message in the input field after inputting a correct value).

Note: This does not apply to unchanged content which is displayed by the platform software by default, such as standard tooltips for the respective programming language.

Note 1: This does not apply to unchanged content which is displayed by the platform software by default, such as standard tooltips for the respective programming language.

Note 2: To be able to move over the shown content, the content must be displayed at the triggering element.

- the triggering of the function during the pressing of the key is essential (an electronic piano or a keyboard simulation, for example),
- during the pressing, the function is automatically reversed upon the release, or
- the function is part of a more complex function that can be canceled (e.g., picking up a drag-and-drop object by pressing the key on the pointing device and completing the action by releasing it again).

Note 1: This does not apply to:

Note 2: The offset of the click areas is defined as the spacing between the farthest point of one element and the nearest point of the other element. The offset is determined in both directions and must be at least 24 px in each case.

Note: This does not apply to:

Use of the keyboard

[Online betrachten](#)

Synonyms: keyboard operation, keyboard interface

See also: [Use of the pointing device](#), [fokus indicator](#), [navigation sequence](#)

It must be possible for all functions which can be initialized using a pointing device, motion control or voice input to also be initialized using the keyboard, as disabled users may not be able to use a pointing device and /or may not see the pointer, may not be able to perform the movement or may not be able to speak. It is also possible that disabled users are unable to use a keyboard, but their assistive technology simulates the keyboard and interacts with the keyboard interface of the operating system and/or the Accessibility API.

In this context, the simulation of a pointing device with the keyboard (e.g., keyboard mouse using the numeric keypad) is not considered a permissible alternative form of operation to the use of the pointing device.

Practical tip: use of the keyboard in Web and desktop applications

Custom elements

The [standard elements](#) of the marking and/or programming language or of the framework used are generally fully keyboard-operable. They should therefore be used with preference.

If [custom elements](#) are used, in terms of the keyboard operability, it is necessary to pay attention to the following in particular:

- Accessibility with the keyboard (e.g. using the tabindex),
- Operability with the keyboard (event handler for the keyboard and/or device-independent event handler),
- Operability conforms to the expectations or has been documented (conforms to expectations regarding the visual presentation and the [role](#) , that is communicated to the [Accessibility API](#) .
- [Focus indicator](#) ,

- Focus handling (e.g. no loss of focus during operation; [Navigation sequence](#)),
- possibly defined [keyboard shortcuts](#) are consistent with those of the platform software and/or do not override those of the platform software.

If a custom element is implemented, it is often recommended that a related default element is used and customized accordingly, as it is then possible to use the basic functionality of the default element.

Drag & Drop

Dragging and dropping elements (drag and drop) can only be done with a pointing device. Designing the alternative form of operation with the keyboard so that it can be used efficiently and in accordance with expectations is recommended. Possible variants include

- [Kontextmenü](#) (e.g. for moving elements to other areas),
- several [buttons](#) , grouped in one [toolbar](#) (e.g. for changing the sequence of elements within an area),
- a button (e.g. for uploading files),
- individual keyboard shortcuts (e.g. adjustment of the size of elements),
- keyboard shortcuts of the platform (e.g. cutting and pasting elements using CTRL+X and CTRL+V),
- use of the arrow keys (e.g. [slider](#)),
- Start and finish with the ENTER key, move with the arrow keys (e.g. drawing a freehand screen).

A combination of the variants is often a good idea (e.g. buttons and keyboard shortcuts).

As the alternative form of operation with the keyboard is not usually visible, it should be described in the application and the Help option.

Control elements that are not permanently visible

Control elements that are shown and hidden when using the application, e.g.

- because they are in tooltips, or
- because they only appear when the keyboard focus is in a particular position,

are not usually operable with the keyboard.

Displaying control elements all the time and avoiding control elements in tooltips, for example, is recommended.

Alternatively, an alternative form of operation must be implemented using the keyboard and described in the Help option and the application. In addition to this, the application must be designed so that it is perceptible with the assistive technology when elements that are not always visible are shown. Blind users, for example, must be able to perceive that a tooltip contains control elements with the screen reader, so that they can use the documented alternative form of operation with the keyboard.

Practical tip: contrast adjustment for desktop applications

In Windows, users can customize the presentation of the colors to suit their needs (Settings > Ease of Access > High contrast). Unlike other operating systems which only allow certain color changes (such as coloring, darkening or inverting the colors), Windows allows you to freely choose the foreground and background colors. In addition to this, it is possible to define individual colors for different element types and/or their status.

With Windows Contrast Adjustment, it is possible to adjust the colors for the following elements and states:

- Text (`SystemColorWindowTextColor`)
- Background (`SystemColorWindowColor`)

- Links (`SystemColorHotlightColor`)
- Highlighted text, selected element (`SystemColorHighlightTextColor`)
- Background of highlighted text or selected elements (`SystemColorHighlightColor`)
- Text of control elements (außer Links) (`SystemColorButtonTextColor`)
- Background of control elements (außer Links) (`SystemColorButtonFaceColor`)
- Disabled elements (`SystemColorGrayTextColor`)

For Windows Contrast Adjustment to work correctly in an application, the following must be considered:

- The foreground and background colors must be defined in such a way that they can be overwritten with Windows Contrast Adjustment. This does not apply to graphics or videos.
- Content whose foreground color is adjusted may not have a background whose color is not adjusted. This applies, for example, to text whose background is a graphic that is not adjusted. This does not apply if the font has a contour in the background color, as the visibility is then ensured through the contour.
- Graphics with a transparent background must be avoided. This does not apply if either the foreground color of the graphic can be adjusted (by using `SystemColorWindowTextColor`, for example), or if the content of graphic has a contour.
- For the element types Text, Links and Form Elements as well as the states Disabled, Highlighted and Selected, the corresponding information about the role and status must be communicated to the Accessibility API. Alternatively, the appropriate colors for the elements and states must be used (for example, `SystemColorGrayTextColor` for disabled elements).
- Images of text must be avoided. Alternatively, the foreground and background colors of the images of text must be adjustable according to the Windows settings.
- Only color-coded contents must be avoided, regardless of the contrast between the colors.
- Page areas, tooltips, pop-ups and control elements that are shown in different background colors should be given a frame so that they also stand out from the background with Windows Contrast Adjustment.
- If the application does not support Windows Contrast Adjustment, the application must offer its own possibility for adjusting the colors with the equivalent functionality. This option must be described in the application and the Help option.
- If your application only supports Windows Contrast Adjustment for a specific configuration (for example, selecting a specific color scheme), it must be described in the application and the Help option.

Example 1: The two following figures show two lines with two pieces of text, two buttons and two links – one in the default presentation (figure on the left), and one with the use of Windows Contrast Adjustment (Contrast no. 1).

- In the figure on the left, the text, button and link are visible in both lines based on the colors used:
 - Text: black font on white background,
 - Button: black font on gray background,

- Link: blue font on white background.
- In the figure on the right, the text, button and link can only be identified correctly in the top line, as they have been programmatically marked as text, button and link:
 - Text: yellow font on black background,
 - Button: white font on black background,
 - Link: blue font on black background.
- In the figure on the right, the text, button, and link in the bottom row are indistinguishable, as they are all displayed in the text color (yellow font on a black background). The reason for the incorrect presentation is that the button and link were not programmatically displayed as such.

text

bu

Figure 6: Text, button and link in the default presentation (left) and with the use of Windows Contrast Adjustment (right).

Example 2: In the two following figures, one operable button (“Send”) and two disabled buttons (“Check” and “Delete”) are shown – one in the default presentation (the figure on the left), and one with the use of Windows Contrast Adjustment (Contrast no. 1).

- In the standard presentation, the two disabled buttons can be seen to be disabled due to the grayed-out colors.
- When using Windows Contrast Adjustment, only the “Check” button is correctly visually identifiable as disabled (green font on black background).
- The “Delete” button is not identifiable as disabled when using Windows Contrast Adjustment, but is shown as operable (white font on a black background). The reason for the incorrect presentation is that it was not programmatically marked as disabled.

Su

Ch

Figure 7: One operable and two disabled buttons in the default presentation (left) and with the use of Windows Contrast Adjustment (right).

Example 3: In the two following figures, four buttons are shown that are labeled with a black icon – one in the default presentation (figure on the left), and one with the use of Windows Contrast Adjustment (Contrast no. 1).

- In the default presentation all four buttons look the same (black icon on white background).
- When using Windows Contrast Adjustment, the four buttons look different because of the different technology used for the presentation of the icon:
 - The first icon is displayed correctly because a font icon was used in which the foreground and background colors are adjusted (white icon on black background). This variant is to be preferred.
 - The second icon is not adjusted (black icon on white background) because it is a graphic without a transparent background. This variant is acceptable.
 - The third icon is not so easy to identify because it is a graphic with a transparent background (black icon on a black background). The icon is perceptible due to its white outline, however. This variant is acceptable.
 - The fourth icon cannot be seen because it is a graphic with a transparent background (black icon on a black background). This variant should not be used.

Figure 8: Four icon buttons in the default presentation (left) and with the use of Windows Contrast Adjustment (right).

Colors and contrasts

168	Color coding	Information conveyed using color or color differences must be communicated to the		
<p>Note: Color information can present the status of a control element, for example (disabled, incorrect, selected, see</p> <p> Must EN 301 549:11.1.3.1, 11.1.4.1 </p>				

Practical tip: color coding

To comply with EN 301 549: 9.1.4.1 and 11.1.4.1, respectively, a distinction must be made between two different forms of color coding:

- the color difference conveys a piece of information,
- the color itself conveys a piece of information.

The color difference conveys a piece of information

Examples:

- The active menu item has a gray background color, all the other menu items have a white background color.
- The text color is black and the link color is blue.

If the colors themselves have no meaning, but only the difference between the colors does, a contrast ratio of at least 3:1 between the colors is sufficient.

The use of another visual method, however, (e.g. icon, font style, size, position, shape, border, underline, text) to reproduce the information conveyed by the color difference is recommended, e.g.

- The active menu item has a bold font style, all other menu items have a normal font style.

- The text is not underlined, but all links are underlined.

Note: EN 301 549: 9.1.4.1 and 11.1.4.1 formulate requirements for visually impaired people who use the application without assistive technology. For users of assistive technology, according to EN 301 549: 9.1.3.1 and 11.1.3.1.1, additional requirements apply with regard to the color coding, e.g.

- To enable blind people to perceive the information conveyed by color difference, this information must be communicated to the [Accessibility API](#) programmatically or in text form.
- To enable users of the Windows Contrast Adjustment to perceive the information conveyed by color difference, this information must be conveyed programmatically (see [Practical tip: contrast adjustment](#)), by another visual means (see above), or in text form.

The color conveys a piece of information

Examples:

- Incorrectly filled out form fields have a red border, correctly filled out form fields have a green border.
- Different background colors are used for messages: red for warning messages, green for success messages and yellow for tips.
- In a financial statement, losses are shown with a red-colored text and profits with black-colored text.

In these cases, the color itself provides a piece of information, and not just the difference between the colors. Therefore, a contrast ratio of at least 3:1 between colors is not sufficient in this case. Another visual method must certainly be used to convey the information, e.g.

- The incorrectly filled out form fields have an error icon (e.g. an exclamation mark in a red circle) and the correctly filled out form fields have a success icon (e.g. a check mark in a green circle). An expressive error message is also displayed in text form in order to comply with EN 301 549, 9.3.3.1 or 11.3.3.1.
- The messages each have a heading that conveys the status (e.g. “Warning”, “Success” and “Tip”).
- In the financial statement, losses are shown with a minus sign in front of the number.

Note: EN 301 549: 11.1.4.1 formulates requirements for visually impaired people who use the application without assistive technology. For users of assistive technology, according to EN 301 549: 11.1.3.1.1, additional requirements apply with regard to the color coding (see above).

Practical tip: anti-aliasing

Regarding the contrast requirements, the WCAG assumes that anti-aliasing has been disabled. However, this is unrealistic, as most users work with anti-aliasing enabled. Due to the anti-aliasing, in case of thin line thicknesses, the actual contrasts can be significantly below the contrasts that are calculated from the color values. Therefore, either the line thickness or the colors should be adjusted in such a way that the contrast ratio (of at least 4.5:1 for text and 3:1 for content of graphics) can also be maintained when anti-aliasing is enabled. Because the anti-aliasing can be configured differently, it is not possible to specify exact values. However, in most cases the following guideline values will help to ensure that the contrast ratios can be maintained:

- minimum line thickness of 2 px or
- doubled contrast ratio at lower line thicknesses (e.g. at least 9:1 instead of 4.5:1).

In this context, it should be noted that a line thickness of 2 px is only achieved for letters above a certain font size; from 25 px for Arial and from 75 px for Times New Roman.

For example: In the following two figures, the letter “x” and a forward slash (“/”) are shown three times in the font style “Times New Roman” and with the font size 16 px. The contrast between the gray and/or black text color defined in the CSS and the white background is:

- Left: 4,5:1,
- Center: 7:1,
- Right: 21:1.

This means that the required minimum contrasts will be maintained throughout the text. In the considerably magnified presentation, however, it can be seen that due to the anti-aliasing, the contrasts calculated for the “x” are only partially achieved with the thicker downward line (diagonal line from the top left to the bottom right) and the horizontal serifs. For the thinner upward line (diagonal line from bottom left to top right), the contrast is clearly below this, e.g. at the most in the lower range at:

- Left: 2,9:1,
- Center: 2,9:1,
- Right: 5,2:1.

For the forward slash, the calculated contrasts are not achieved at any point.

- Left: maximum 2,4:1, average approx. 2,0:1,
- Center: maximum 2,5:1, average approx. 2,1:1,
- Right: maximum 3,5:1, average approx. 2,3:1.

Figure 9: Effect of anti-aliasing on contrasts using the example of “x/” in normal size.

Figure 10: Effect of anti-aliasing on contrasts using the example of “x/” with resizing.

Practical tip: special characters

When using special characters, different use cases must be distinguished between in terms of the communication of the characters to the Accessibility API:

Decorative special characters

Purely decorative special characters are marked so that they are not communicated to the Accessibility API. The same rules apply to them as to [layout graphics](#) .

Examples:

- Button with the label “Next »”: The two forward arrows are purely decorative. The button should have the Accessible Name “Next”.
- Form field label “- - Location - -”: The dashes are purely decorative. The form field should have the Accessible Name “Location”.

Non-purpose-related special characters that contain content

Special characters which are not used according to their meaning are to be accompanied by an expressive alternative text. The same rules apply to them as to [graphics](#) .

Examples:

- Button with the label »: The two forward arrows visually convey the information “Next”. The button should have the Accessible Name “Next”.
- Button with the label x: The multiplication symbol visually conveys the information “Close”. The button should have the Accessible Name “Close” (possibly with an indication of what is being closed, e.g. “Close window”).

Note: If used as a [required field label](#) , the asterisk (“*”) is not considered to be non-purpose-related.

Purpose-related special characters that contain content

Special characters which are used according to their meaning can be used, provided the character is output correctly using the assistive technology. Otherwise, it should be accompanied by expressive alternative text.

Examples:

- Mathematical formula “ $3+5 > 5-3$ ”: The two arithmetic operators as well as the larger character are output correctly by the assistive technology and can therefore be used.
- Text with the ordinal characters “^a” and “^o”: The assistive technology does not output the two characters at all and/or does not do so correctly, and therefore the two characters require an alternative text.
- The word “guest” with a ligation of s and t. Most screen readers do not know the ligation, and instead of “guest”, only state “gu” and a space.

Figure 11: The word “guest” with a ligation

Special-purpose characters should be used sparingly. It is recommended to use a character which is output in concise form by the assistive technology.

Examples:

- A quote can be given different quotation marks. The “ character is output by the assistive technology, for example, as “typographical quotation mark, top” or “typographical quotation mark, right”. The ” character, by contrast, is output as “inverted commas” or “quotation mark”, and is therefore to be preferred.
- The sentence “I prefer the character »#« to “#”” (see the following figure) is output by the screen reader, for example, as “I prefer the double bracket black hashtag with white X double bracket character to lower typographical quotation mark 3D narrow right-pointing arrow head inverted commas”.

Figure 12: Sentence with special characters is output by the screen reader in a difficult to understand way

Practical tip: font style and text formatting

To make texts easy to read, a legible font style and text formatting should be chosen. In this respect, the following should be taken into account:

- The most readable fonts are those from the humanist sans serif category.
- Ligations should be avoided.
- The minimum font size for text blocks should be 22px.
- The minimum font size for additional text (e.g. footnotes) should be 17px.
- Narrow and wide fonts should be avoided.
- Small and large character spacing should be avoided.

- Thin and thick font styles should be avoided.
- The line spacing should be at least 120% of the font size.
- Upper and lower case lettering should be used according to the orthography rules. The exclusive use of upper or lower case lettering should be avoided.
- Upper and lower case lettering should be used according to the orthography rules. The exclusive use of upper or lower case lettering should be avoided.
- Small caps should be avoided.
- Highlighting should be used sparingly. A bold font style should be used for highlighting.
- Italic font styles or underlining should be avoided. Note: Links should be underlined.
- The text should be left-aligned. The use of justify should be avoided.

You can find more information at: <https://www.leserlich.info> (External Link)

:

Focus indicator

[Online betrachten](#)

Synonyms: Focus, focus frame, focus appearance

See also: [Use of the keyboard](#) , [text cursor](#)

The focus indicator displays which element currently has the keyboard focus (see DIN EN ISO 9241-161: 8.37).

The focus indicator is usually displayed with a border around the focused element. Other focus indicators are also permitted, provided that they meet the requirements, e.g.

- Inverting of foreground and background color,
- Changed background color,
- Changing the size of the element,
- Superimposing of a graphical element, such as a side bar.

In certain cases, several focus indicators can be displayed:

- Example 1: When a selection list receives the focus, a focus indicator can be displayed around the entire list. A focus indicator must also be displayed with the current list entry.
- Example 2: With a combined input field, the focus can be on the input field as well as on the selection list.
- Example 3: If an interactive element receives the focus within a page area, then the page area can also be shown as focused.
- Example 4: The title bars of all application windows that do not have the focus are shown grayed out.

In some cases, the focus indicator can be identical to the selection marker (i.e. the marking of the selected option, see [Element status](#)), if the focused element is identical to the selected element:

- Example 1: A [selection list](#) without multiple selection has a focus indicator on the focused list entry. This indicator can serve as a selection marker at the same time, as the focused list entry is identical to the selected list entry. If this selection list does not also have a focus indicator for the entire list, however, to be able to detect whether the selection list is focused, it is necessary to ensure that the selection marker in the focused state of the selection list differs clearly from the selection marker in the non-focused state of the selection list (e.g. minimum contrast ratio 3:1).
- Example 2: A selection list without multiple selection has a focus indicator on the focused list entry, e.g. a border. This focus indicator is not used simultaneously as a selection marker. A different background color, for example, is used as the selection marker. When navigating through the list entries, both the focus indicator and the selection marker are moved. In this case, an additional focus indicator for the entire list or a differentiation of the selection marker in the focused and non-focused state is not necessary, as the focusing and selection can be perceived independently of each other.

- Beispiel 3: A [multiple selection list](#) has a focus indicator that surrounds the entire list. Since the focused list entry does not match the selected list entries in the case of the multiple selection list, the focus indicator and selection marker must be marked separately for the list entries (e.g., as shown in example 2 with a border and a different background color).

Presentation

No.	Property	Description	Classification	Reference
186	General	The focus indicator must be visible at each navigation step.	Must	EN 301 549: 9.2.4.7, 11.2.4.7

Practical tip: focus indicator

The focus indicator must have sufficient contrast, and should be designed consistently at the same time. With applications that have different background colors, this can be achieved by using a two-color border (e.g. black and 05.15.2023 Page 68 of 317 white) that has sufficient contrast against each background. A two-color focus indicator is also useful with control elements on gradients or graphics.

For example: Two buttons on a color gradient from white to black. The top button is currently focused. The focus indicator consists of a black border (inside) and a white border (outside), which means that it is always easy to see, regardless of the background color. It is the standard focus frame offered by Google Chrome.

Figure 13: Two-color focus indicator

Text cursor

[Online betrachten](#)

Synonyms: Cursor

See also: [Use of the keyboard](#) , [Focus indicator](#)

The text cursor displays the position in an input field (see DIN EN ISO 9241-161: 8.8). The text cursor is typically displayed by a vertical line at the point at which the text is entered, edited or deleted.

Presentation

No.	Property	Description	Classification	Reference

Programming/interfaces

[Accessibility API](#)).

Note 2: If filling out a form field group is labeled as required without the necessity for every field of the group to be filled out, the programmatic required field labeling should only take place at the group and not at every field. In this case, care must be taken to ensure that the required field label of the group is communicated correctly to the Accessibility API.

No.	Property	Description	Classification	Reference
201	Status	The required field status must be communicated to the Accessibility API (see		

Note 1: The programmatic required field labeling should take place using an attribute of the programming language provided for this purpose or using the textual supplement in the Accessible Name of the form field (e.g. asterisk). The redundant programmatic marking of the required fields with attribute and supplement in the Accessible Name label should be avoided.

| Must | EN 301 549:9.1.3.1, 11.1.3.1, 9.3.3.2, 11.3.3.2, 9.4.1.2, 11.4.1.2 |

Practical tip: required field label

Required fields can be labeled with a corresponding textual supplement, such as “required field” or “required”. If the majority of the fields are required, the fields that do not need to be filled out can alternatively be labeled with “optional”, for example.

The required fields can also be marked with a symbol. The asterisk (“*”) has established itself for this purpose, in which it can be assumed, at least in specialist applications, that it is known to all users. If another character is used, its meaning should be explained at the beginning of the form.

Practical tip: programmatic label of required fields in Web applications

Screen reader output

- JAWS: required invalid entry | required [after the role and before the value]
- NVDA: required invalid entry | required [after the role and before the value]
- Windows Narrator: required invalid | required [after the value]

Note: A required field which is not filled out but which has been marked with **required** is in the incorrect status due to the HTML specification, and is therefore output by the screen readers as “invalid entry” and/or “invalid”. The problem does not occur when using **aria-required**.

HTML

Required fields can be marked with the **required** attribute..

- Form fields that have been marked as required are automatically validated by the browser and will have an incorrect status if they have not been filled out.
- Form fields that have been marked as required are not automatically visually identifiable as required fields. They have a tooltip, (e.g. “Please complete this field”), which is not perceptible to users of the keyboard and with the screen reader, however, as it is only displayed in the case of a mouse over.
- By default, a form which has required fields that have not been filled out cannot be submitted. Instead, the focus is placed in the first incorrect field and the tooltip is displayed as an error message and output by the screen reader as a warning message (analogous to **role=alert**). These error messages are not accessible for the following reasons:
 - When exiting the field, the error message is hidden automatically and cannot be displayed again.
 - Several browsers automatically hide error messages after a few seconds, even if the focus is in the field (with Chrome and Edge, for example).
 - The error message is only displayed at the first incorrect field. Other required fields that are not filled out are not to be perceived as incorrect.

Therefore, when using **required**, the following should be considered:

- Required fields must also be visually labeled as such.
- The visual required field label should be marked so that it is not output by the screen reader to avoid the redundant output.

- The application should continuously display its own error messages for all required fields that have not been filled out.

Note: In the practical tip on [radio buttons](#) and [checkboxes](#) , the particularities regarding their marking up as required fields are explained.

Further information [4.10.5.3.4 The required attribute - HTML Standard \(whatwg.org\)](#)

ARIA

Required fields can be marked with the `aria-required=true` attribute.

- Form fields that have been marked with `aria-required=true` are not automatically validated by the browser and will not have an incorrect status if they have not been filled out. The incorrect status can be communicated with `aria-invalid=true` .
- Form fields that have been marked with `aria-required=true` are not automatically visually identifiable as required fields.

Practical tip: headings in Web applications

Screenreader output

- JAWS: Heading level [number] [label]
- NVDA: Heading level [number] [label]
- Windows Narrator: Heading level [number] [label]

HTML

Headings are marked with the HTML elements

,
,
,
,

and

. In this respect, the following should be taken into account:

- Headings should be concise, clear and expressive, as for users of screen readers, they are the primary method of navigating and perceiving the page structure.
- The headings should be nested correctly from a hierarchical perspective, i.e. an `<h1>` should be followed by `<h3>`-headings whose sections can in turn contain `<h3>` headings. According to the HTML specification, no heading levels may be skipped, for example, `<h3>` should not be followed by `<h4>`, `<h5>` oder `<h6>`.

- The main heading (`<h1>`) should describe the purpose of the respective page (and not just include the application name, for example).

Headings can be grouped within the `<hgroup>` elements along with paragraphs (`<p>`-Element) to specify a caption or an alternative heading, for example. This grouping is not perceptible with any of the screen readers for Windows, i.e. the content of the `<p>` element is output as normal text, as according to the "HTML Accessibility API Mappings", the `<hgroup>` element does not have any semantics.

Further information: [4.3.6 The h1, h2, h3, h4, h5, and h6 elements - HTML Standard \(whatwg.org\)](#) , [4.3.11 Headings and outlines - HTML Standard \(whatwg.org\) \(External Link\)](#) , [Headings | Web Accessibility Initiative \(WAI\) | W3C](#)

ARIA

If the heading is not implemented with the HTML elements, it is also necessary to take account of the following:

- The role is communicated with `role=heading`.
- The heading level is communicated with `aria-level` Only the numbers from 1 to 6 should be used. With numbers greater than 6, JAWS outputs the heading with the level 2.
 - With numbers greater than 6, JAWS outputs the heading with the level 2.
 - With numbers greater than 9, NVDA and Windows Narrator output the heading with the level 2.
- The labeling should take place using text content.

Further information: [heading role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

Label

[Online betrachten](#)

Synonyms: Designation, form field label, name, accessible name

Siehe auch: [font](#) , [text](#) , [graphik](#) , [form](#) , [group](#) , [description](#) , [error message](#) , [required field label](#)

Labels are used for the identification of control elements (see DIN EN ISO 9241-161: 8.21).

A label consists of a short, descriptive text or an expressive graphic and/or a combination of text and graphic.
The label can be situated inside the element or adjacent to the element which is labeled.

Label:

Practical tip: labeling in Web applications

Screenreader output

- JAWS: **[Label]** [role] [required field note] [validation note] [value] [description] [error message] [screen reader operating note] [keyboard shortcut note]

- NVDA: **[Label]** [role] [required field note] [validation note] [description] [keyboard shortcut note] [value]
- Windows Sprachausgabe: **[Label]** [role] [value] [required field note] [validation note] [keyboard shortcut note]

Please note:

- The label is output by the screen readers first, immediately before the role.
- Only one group label is output before the label, if available.
- During the reading with the [virtual cursor](#), the label is output at the element itself or where it is located in the source code, depending on the control element. To ensure that labels can also be assigned to the control elements correctly in the case of reading with the virtual cursor, the label should be located in the source code in the element (e.g. with links and buttons), directly in front of the element (with form fields other than radio buttons and check boxes) or directly after the element (with radio buttons and check boxes).

HTML

In HTML, the labeling method depends on the element type: # Links, buttons (that are marked with the `<button element>` are labeled using their text content or the alternative text of the graphic, # Buttons (that are marked with the `<input>` element) are labeled using the value attribute. # Form elements are labeled with the `<label>` element. # Form field groups (`<fieldset>`) are labeled with the `<legend>` element. # Graphics (``) are labeled with the `alt` attribute. # Figures (`<figure>`) are labeled with the `<figcaption>` element. # Tables are labeled with the `<caption>` element. # iFrames and regions (e.g. `<nav>` and `<section>`) are labeled with the title attribute. Certain elements may not be labeled (e.g. `<div>` or ``).

Further information: [4.10.4 The label element - HTML Standard \(whatwg.org\)](#), [Providing Accessible Names and Descriptions | APG | WAI | W3C](#), [Labeling Controls | Web Accessibility Initiative \(WAI\) | W3C](#), [4. Accessible Name and Description Computation - HTML Accessibility API Mappings 1.0 \(w3.org\)](#)

ARIA

In ARIA, it is possible to communicate labels with the attributes `aria-labelledby` and `aria-label`.

- With `aria-labelledby` reference can be made to the IDs of visible or invisible labels.
- With `aria-label` the label can be specified directly in text form.
- Certain elements that are marked with ARIA roles can also be labeled with their text content. This also applies to the `button`, `link`, `checkbox`, `radio`, `option` and `tab` roles. In the ARIA specification, these elements are marked with “Name From: content”.
- Certain elements that are marked with ARIA roles must be explicitly labeled (generally with `aria-label` or `aria-labelledby`) Labeling using the text content is not possible. This also applies to the following roles: `listbox`, `combobox`, `dialog`, `form`, `application`, `grid`. In the ARIA specification, elements that have to be labeled are marked with “Accessible Name Required: True”. Whether an element can be explicitly labeled can be seen in the ARIA specification at “Name From: author”.

- A label can also be marked with `role=caption` caption, and then serves the purpose of the labeling of tables (`role=grid`, `role=table`, `role=treegrid`) and figures (`role=figure`), as long as the label is the first (or with `role=figure` the final) child element of the element to be labeled. Regardless of the marking with `role=caption`, reference to the label should be made with `aria-labelledby`.
- Certain ARIA roles cannot be labeled, such as `generic`, `paragraph`, `presentation`, `code`, `insertion`, `deletion`, `emphasis`, `strong`, `subscript` and `superscript`. In the ARIA specification, these elements are marked with “Name From: prohibited”. Elements with these roles may contain text, however.
- Reference can be made to hidden elements using `aria-labelledby`, e.g. those that have been marked with `display:none` or `hidden`. The contents of the hidden elements are used to label the element with `aria-labelledby`. In such cases, however, the use of `aria-label` is recommended..

Further information: [aria-label property - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)
, [aria-labelledby property - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

General information

- Each control element must have a label which is communicated to the Accessibility API as the Accessible Name. This also applies if the element has no visible label.
- The label should be concise and expressive.
- The Accessible Name should not contain any change of language or structured content, as this is not perceptible with the assistive technology.
- For each element, it is only possible to communicate a label to the Accessibility API using one method. If several methods are used, only the label whose method has the highest priority is used as the Accessible Name. The priority of the methods is defined as follows:
 1. `aria-labelledby`,
 2. `aria-label`,
 3. HTML labeling methods (e.g. `<label>`, `<caption>`, `value`, `alt`, if applicable to the element),
 4. text content (if permissible for the element),
 5. `title`,
 6. `placeholder` (only for input fields).
- Elements should not be labeled using the `title`- or `placeholder`attribute, as these two attributes, which are actually intended for the communication of a description and/or an input instruction, are used only as a label if no correct label is available. This is a repair mechanism which is designed to ensure that an element is not output without a label.

- If the labeling of a control element occurs explicitly using an attribute (for example, `aria-label`, `aria-labelledby`, `id`, which are referenced via `<label for>` the attribute must be situated on the element that receives keyboard focus and has the role of the element to be labeled. The control element cannot be labeled by attribute if the attribute is situated on a parent or child element.
- Text content which is shown `before` or `after` as pseudo-elements using the CSS selectors are taken into account when determining the label. To avoid this, they should be marked with `aria-hidden=true`.
- If a reference is made to a form field using `aria-labelledby`, the value of the form field (not its label, however) is taken into account when determining the labeling of the element with `aria-labelledby`.
- ARIA elements must generally be labeled with an ARIA method (e.g. `aria-label` or `aria-labelledby`) or using their text content (if permissible for the respective role). In this way, for example, an ARIA check box cannot be labeled with the `<label>` element and an ARIA graphic cannot be labeled with the `alt` attribute. An exception is presented by ARIA elements whose underlying HTML elements allow for the appropriate HTML labeling method. Accordingly, a combined input field (`<input role=combobox>`) can be labeled with the `<label>` element because the HTML element `<input>` can be labeled with the `<label>` element.
- The visible label should not be marked with `aria-hidden=true` true, even if an Accessible Name is available, to ensure that the text-to-speech works using the mouse.
- The visible label should be used as an Accessible Name to avoid a repeated output of the label with the text-to-speech feature.
- For form fields, the Accessible Name in the source code should be immediately in front of the element, except for radio buttons and check boxes, in which case the Accessible Name in the source code should be immediately behind it. This is important, to ensure that the label can be assigned to the form fields correctly when reading with the virtual cursor of the screen reader. # Depending on the type of element, the text content of elements is also imperceptible with the virtual cursor of the screen reader if the elements are explicitly labeled (e.g. with `aria-label` or `aria-labelledby`).
 - In the case of control elements (such as links and buttons), the text content should be used as a label. It must otherwise be ensured that all the information contained in the text content is also available in the Accessible Name.
 - In the case of grouping elements (such as form field groups, regions, lists, or tables), their contents are perceptible with the virtual cursor, even if they are explicitly labeled. These elements should therefore be labeled explicitly so that their purpose is recognizable.

Description

[Online betrachten](#)

Synonyms: Note, Help, Operation note, Input instruction, Instruction, Accessible Description

Siehe auch: [font](#) , [text](#) , [label](#) , [error message](#) , [required field label](#) , [tooltip](#) , [help and support](#)

A description contains additional information on the use and operation of the application (see DIN EN ISO 9241-161: 8.19).

Descriptions can refer to a control element, an area, a screen, or to the entire application. A description consists of an explanatory text, a graphic or a combination of text and graphic.

Descriptions can be

- permanently visible,
- are dynamically shown and hidden during operation (e.g. when hovering with a pointing device, when receiving focus with the keyboard or after enabling a control element).

Presentation

[labels](#) of the control elements are sufficient. Descriptions may be necessary, for example, for an input field at which a particular input format is required.

Note: Therefore, for example, a button should not be described by its appearance or position, but by its label.

Note: Descriptions for a form field, for example, can be displayed to the right or below the field.

Practical tip: descriptions in Web applications

Screenreader output

- JAWS: [label] [role] [required field note] [validation note] [value] **[description]** [error message] [screen reader operating note] [keyboard shortcut note]
- NVDA: [label] [role] [required field note] [validation note] **[description]** [keyboard shortcut note] [value]
- Windows Narrator: [label] [role] [value] [required field note] [validation note] [keyboard shortcut note]

Please note:

- The description tends to be given by JAWS and NVDA at the end, and certainly after the label and the role.
- The description is not output by Windows Narrator.
- JAWS and NVDA can be configured so that the description is not output. This feature is used by experienced users of screen readers in order to perceive the content more efficiently. Therefore, only additional information should be included in the description.
- When reading with the [virtual cursor](#) descriptions are not generally output by the screen reader. The output of the descriptions only occurs with the TAB navigation. Therefore, only additional information should be included in the description, and the description should only be used with control elements that can receive the keyboard focus.

HTML

In HTML, most of the control elements can only be given a description using the title attribute. However, the title attribute is not accessible for the following reasons:

- When using the browser zoom, the tooltip which is displayed using the title attribute is not scaled.
- During the keyboard navigation, the tooltip is not shown (except in the Edge browser) and is therefore imperceptible to sighted keyboard users.
- It is not possible to move over tooltips with the mouse.
- In certain browsers (such as Firefox), the tooltips cannot be hidden without moving the focus away.
- The tooltips cannot be displayed on mobile devices or can only be displayed with difficulty. For these reasons, the title attribute should be avoided.

In HTML, in addition to the **title** attribute, a few elements can be given a description using another method:

- Buttons marked with the `<input type=button|reset|submit>` element through the value attribute, unless this is already used for the Accessible Name,
- Buttons marked with the `<summary>` element through their text content, unless this is already used for the Accessible Name,
- Tables with the `<caption>` element, unless this is already used for the Accessible Name.

This is designed to ensure, however, that the visible label is at least perceptible by the assistive technology as a description if it is not output as a label (Accessible Name). As the visible label is required to correspond to or at least be contained in the Accessible Name (EN 301 549: 9.2.5.3), none of the three methods should be used for marking up a description.

Further informationen: [3.2.6.1 The title attribute - HTML Standard \(whatwg.org\) \(External Link\)](#), [Providing Accessible Names and Descriptions | APG | WAI | W3C](#), [4. Accessible Name and Description Computation - HTML Accessibility API Mappings 1.0 \(w3.org\)](#)

ARIA

In ARIA, it is possible to communicate descriptions with the attributes `aria-describedby` and `aria-description`.

- With `aria-describedby`, reference can be made to the IDs of visible or invisible descriptions.
- With `aria-description`, the description can be specified directly in text form. The attribute is only defined with ARIA 1.3, which means it is not yet supported by older assistive technology.
- Reference can be made to hidden elements using `aria-describedby`, e.g. those that have been marked with `display:none` or `hidden`. The contents of the hidden elements are used for the description of the element with `aria-describedby`. In such cases, however, the use of `aria-description` is recommended.

Additional ARIA attributes can be used for the communication of further information to the Accessibility API that has a descriptive character, but is not a description (Accessible Description):

- Error messages with `aria-errormessage`,
- Placeholders with `aria-placeholder`,
- Information about keyboard shortcuts with `aria-keyshortcuts`,
- Reference to a detailed description with `aria-details`.

Please note: Although the `aria-roledescription` attribute sounds as though it could be used to describe the role of the element, this is not the case. With `aria-roledescription`, the role of the element is overwritten, which means that the attribute should be used with caution.

Further informations: [aria-describedby property - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#), [aria-description property - Accessible Rich Internet Applications \(WAI-ARIA\) 1.3 \(w3c.github.io\) \(External Link\)](#)

General information

- Although a description that is programmatically communicated as an Accessible Description can be more detailed than the label, it should also be concise and meaningful. The description should not be redundant to the label.
- In addition, the Accessible Description should not contain any change of language or structured content, as this is imperceptible with the assistive technology.

- Longer descriptions or descriptions with changes of language or structured content should be implemented in such a way that they can be read with the virtual cursor of the screen reader, i.e. they are available in text form. From the corresponding control element, reference can be made to the detailed description using `aria-details` details or in a short Accessible Description.
- For each element, it is only possible to communicate a description to the Accessibility API using one method. If several methods are used, only the description whose method has the highest priority is used as the Accessible Description. The priority of the methods is defined as follows:
 1. `aria-describedby`,
 2. `aria-description`,
 3. visible label in the case of buttons and tables, unless used for the Accessible Name (see above),
 4. `title`.
- If the description of a control element occurs explicitly using an attribute (for example, `aria-description`, `aria-describedby`, `title`), the attribute must be situated on the element that receives keyboard focus and has the role of the element to be described. The control element cannot be described by attribute if the attribute is situated on a parent or child element..
- Text content which is shown `before` or `after` as pseudo-elements using the CSS selectors are taken into account when determining the description. To avoid this, they should be marked with `aria-hidden=true`.
- If a reference is made to a form field using `aria-describedby`, the value of the form field (not its label, however) is taken into account when determining the description of the element using `aria-describedby`.
- The visible description should not be marked with `aria-hidden=true`, even if an Accessible Description is available, to ensure that the text-to-speech works using the mouse.
- The visible label should be used as an Accessible Description to avoid a repeated output of the description with the text-to-speech feature.
- To ensure a meaningful reading sequence with the virtual cursor of the screen reader, descriptions should be in the source code, at or within the element which is described, e.g.
 - Input instructions in a form as a child element at the beginning of the `<form>` element,
 - Input instructions of a form field directly before or after the form field, but after the label of the field under all circumstances.
- Die Attribute `title`, `aria-describedby` and `aria-description` attributes are global attributes, i.e., they can be used with any HTML element and/or ARIA role. It should be noted, however, that most screen readers do not output the Accessible Description when reading with the virtual cursor, which means that these three attributes should only be used for control elements that receive the keyboard focus. There is no problem in using `aria-describedby` with other elements, provided that the description text to which the attribute refers is also readable with the virtual cursor, i.e. it has not been hidden (e.g. with `hidden` or `aria-hidden=true`).

Practical tip: text

Application that does not support the virtual cursor

Longer texts (guideline: 80 to 400 characters) without a text structure (i.e., continuous text only, without lists, tables, headings, etc.) in applications that do not support the [virtual cursor](#) , should

- receive the focus in multiple TAB steps (approximately 80 characters per TAB step), or
- be marked so that they are readable with the virtual cursor, or
- be offered in a linked document which can be read with the virtual cursor (e.g. HTML, PDF, RTF).

Long texts (from approx. 400 characters) or texts with structure (e.g. lists, tables, headings) should

- be marked so that they are readable with the virtual cursor, or
- be offered in a linked document which can be read with the virtual cursor (e.g. HTML, PDF, RTF).

Applications with several TAB steps on text and other non-operable elements should have a mode to disable such unnecessary navigation steps for sighted keyboard users. This mode and its enabling should be described in the accessibility instructions.

Application that supports the virtual cursor

If copying individual text content in the application context may be relevant, this should also be possible with the keyboard. The following requirements must then be met for the text content:

- the text content is focusable with the keyboard, # the [Textcursor](#) is visible within the text,

- within the text, it is possible to navigate with the arrow keys to determine the starting point of the highlighting,
- the text can be highlighted with SHIFT + arrow keys,
- the highlighted text can be copied using CTRL+C (also via the context menu if necessary), and is saved to the Windows clipboard after copying.

To accomplish this, read-only [input fields](#) can be used.

If the entire content of a section of text must be copyable, a button for the copying of the text content can be implemented. Pressing the button should result in the text being copied to the clipboard.

Applications with several TAB steps on copyable pieces of text should have a mode for disabling such navigation steps. This mode and its enabling should be described in the accessibility instructions.

No.	Property	Description	Classification	Reference
305	Role	The “graphic” role must be communicated to the Accessibility API (see		

Practical tip: graphics in Web applications that communicate a role, status, or value

HTML

The HTML standard elements do not have to be considered with regard to the graphics that communicate information about role, status or value, because the corresponding information is automatically communicated correctly by the browser to the Accessibility API.

ARIA

In the case of custom elements that are implemented with ARIA roles and ARIA attributes, the graphics that convey information about the role, status, or value should be marked as layout graphics. Instead, the information should be programmatically communicated, e.g. with the following attributes:

- **role** for the role,
- **aria-valuenow** and **aria-valuetext** for the value,
- **aria-required** for required fields,
- **aria-invalid** for incorrect form fields,
- **aria-checked** and/or **aria-selected** for the “selected” status,
- **aria-disabled** for disabled control elements,
- **aria-pressed** for the “pressed” and/or “not pressed” status,
- **aria-expanded** for the “reduced”/“hidden” and/or “expanded”/“shown” status
- **aria-haspopup** for elements that show a menu, selection list, tree structure, table, or dialog when they are enabled,
- **aria-sort** for the sorting direction,
- **aria-current** for marking the current element.

Insofar as no ARIA attribute exists for the relevant information, the information should be communicated in text form as part of the label or description of the element.

Further information: [Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

Practical tip: graphics in Web applications

Screen reader output

- JAWS: [alternative text] **graphic**
- NVDA: **Graphic** [alternative text]
- Windows Narrator: [alternative text] **image**

HTML and ARIA

The way in which graphics are marked and labeled depends on the method which is used for the presentation of the graphic:

- Graphics marked with the **** element are labeled with the **alt** attribute.

- Buttons with graphic labeling which are marked with the `<input type=image>` element are also labeled with the `alt` attribute.
- All other graphics should be marked with `role=img` and explicitly labeled with `aria-label` or `aria-labelledby`. This also applies, for example, to the elements `<svg>` and `<canvas>`, CSS background graphics, font icons and letters that are used in a graphical context (e.g. “x” for “deleted”).
- Graphics for list characters (`list-style-image`) cannot be provided with an alternative text or marked as layout graphics and should not therefore be used.

In this case, the following exceptions apply:

- Graphics that are used for the labeling of control elements can be marked as layout graphics. Instead, the control element is expressively labeled (e.g. `<button title=delete></button>`, `<button aria-label=delete></button>`). If the control element is labeled using `aria-label` or `aria-labelledby`, the contained graphic automatically becomes the layout graphic, and does not have to be marked separately as such.
- The screen readers provide the relevant information concerning the elements (label, role, status, value) which are located within `<svg>` and `<canvas>` if the respective `<svg>` and/or `<canvas>` element is not marked as a graphic. This means, for example, that the `<svg>` and/or `<canvas>` element can be labeled as a group with `role=group` and with `aria-label` or `aria-labelledby`. In this case, it is not directly perceptible with the screen reader that it is a graphic (this information can be communicated indirectly through the labeling of the group, however), but it is possible to communicate detailed and structured text alternatives within the graphic elements, in the case of diagrams, for example.
- Font icons or graphics that are shown `before` or `after` as pseudo elements using the CSS selectors may also be provided with an alternative text directly in the CSS in the future ([1.2. Alternative Text for Accessibility - CSS Generated Content Module Level 3 \(w3.org\) \(External Link\)](#)). At present, this is not yet reliably supported by the assistive technology, however.

Practical tip: layout graphics in Web applications

Screen reader output

None

HTML and ARIA

The way in which layout graphics are marked depends on the method which is used for the presentation of the graphic:

- Graphics that are marked with the `` element should be marked with a blank alternative text as a layout graphic (``).
- Graphics that are marked with the `<svg>` element should be marked with `aria-hidden` as a layout graphic (`<svg aria-hidden=true>`).
- Graphics that are marked with the `<canvas>` element should be marked with `aria-hidden` as a layout graphic (`<canvas aria-hidden=true>`).
- Font characters that are purely decorative should be marked as a layout graphic with `aria-hidden` (`~~~~`).
- Font icons or graphics that are shown **before** or **after** as pseudo-elements using the CSS selectors should be marked as layout graphics with `aria-hidden` (``). In the future, it will be possible for these pseudo-elements to be directly marked as layout graphics in the CSS ([1.2. Alternative Text for Accessibility - CSS Generated Content Module Level 3 \(w3.org\) \(External Link\)](#)). At present, this is not yet reliably supported by the assistive technology, however.
- Font icons should be marked as a layout graphic with `aria-hidden` (`i`).
- Graphics for list characters (`list-style-image`) cannot be provided with an alternative text or marked as layout graphics and should not therefore be used.
- CSS background graphics (`background-image`) are automatically layout graphics.
- Other CSS graphics (e.g. those created with `border`) are automatically layout graphics.

Layout graphics should not receive the keyboard focus, i.e. the graphic itself or its descendant elements should not be marked with `tabindex` or as control elements (e.g. `<button>`).

Further information: [Decorative Images | Web Accessibility Initiative \(WAI\) | W3C](#)

Progress bar

[Online betrachten](#)

Synonyms: Progress display

See also: [Slider](#) , [graphic](#)

A progress bar shows how far a process has progressed (see DIN EN ISO 9241-161: 8.30). The progress can be displayed in text form, graphically (e.g. progress bar) or as a combination of graphics and text. The presentation of the progress bar changes automatically until the process is complete.

Practical tip: progress bar in Web applications

Screen reader output

Progress bar with value:

- JAWS: [label] **progress bar** [value] percent
- NVDA: [label] **progress bar** [value]
- Windows Narrator: [label] [value in %] percent **status bar** current value [value] lowest value [minimum value] highest value [maximum value]

Progress bar without value:

- JAWS: [label] **progress bar** 0 percent
- NVDA: [label] **busy status**

- Windows Narrator: [label] 0 percent **status bar** current value 0 lowest value [minimum value] highest value [maximum value]

Please note:

- JAWS misleadingly outputs the value with the addition “percent”, without converting it into a percentage value.
- The updating of the progress bar is not automatically perceptible with JAWS and Windows Narrator.
- NVDA automatically outputs the progress bar update regardless of the focus position with short beeps whose pitch represents the level of the value.

HTML

The progress bar should be implemented with the HTML element `<progress>`.

The current value is set with the `value` attribute. If no `value` attribute is specified, the progress bar is indeterminate and only indicates that progress is being made without being able to show its extent.

The maximum value is set with the `max` attribute. It should be noted that its value is imperceptible with many forms of assistive technology. The minimum value is always 0.

The label should be linked to the progress bar with the `<label for=ID>` element.

The `<progress>` element can contain different child elements depending on the HTML specification. These are neither visually perceptible nor output by the assistive technology, however.

Further information: [4.10.13 The progress element - HTML Standard \(whatwg.org\)](#)

ARIA

If the progress bar is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=progressbar`.
- The current value can be specified with `aria-valuenow`. If the value is not specified, the progress bar is indeterminate.
- `aria-valuetext` can also be used to specify a value in text form which should be then output by the assistive technology instead of the value in `aria-valuenow`.
- The minimum and maximum values can be specified with `aria-valuemin` and `aria-valuemax`.
- The labeling can take place with `aria-label` or `aria-labelledby`.
- The presentation of the progress bar should be verified in Windows High Contrast mode.

A window contains all the currently visible elements of the application (see DIN EN ISO 9241-161: 8.51). A window can contain the following elements:

- Title
- Working area (with menu if necessary),
- Status bar.

Note: All the requirements concerning the window refer to desktop applications only. For Web applications, the browser is the window. The Web application itself does not contain any windows.

Examples:

The diagram illustrates a window structure. It consists of a white rectangular area at the top, which is the title bar, and a large black rectangular area below it, which is the working area. The text 'Title bar' is written in large, bold, black font within the white area. The text 'Working area' is written in large, bold, white font within the black area.

Toolbar

[Online betrachten](#)

Synonyms: Symbols bar, toolbox, command bar tab

See also: [Menu](#) , [group](#) , [menu button](#)

Toolbars serve the grouping of interactive elements for the editing of content or data (see DIN EN ISO 9241-161: 8.49).

A toolbar contains interactive elements (in most cases, buttons or toggle switches) that are grouped visually with a border, for example. The contents of the toolbar are usually arranged horizontally above or below the area, the contents of which are edited with the elements of the toolbar. The elements of the toolbar can be arranged in several lines. For toolbars with several buttons, icons are often used to label the buttons due to space-related constraints.

Figure 20: Toolbar for setting the font style properties

Presentation

Only those requirements that are directly related to the toolbar are described below. Requirements regarding interactive elements within the toolbar are described at the respective element.

No.	Property	Description	Classification	Reference

- NVDA: **Toolbar ... outside the toolbar**
- Windows Narrator: -

HTML

There is no element for toolbars in HTML. Instead of this, buttons and other control elements can be grouped in a list (`<menu>` and ``), a labeled region (e.g. `<section>`) or form field group (`<fieldset>`, labeled with `<legend>`). The navigation between the elements then takes place with the TAB key and not the arrow keys. To support the efficient keyboard navigation, it should be possible to skip the region and/or form field group (see practical tip on efficient navigation).

Further information: [4.4.7 The menu element - HTML Standard \(whatwg.org\) \(External Link\)](#), [4.3.3 The section element - HTML Standard \(whatwg.org\) \(External Link\)](#), [4.10.15 The fieldset element - HTML Standard \(whatwg.org\)](#)

ARIA

When implementing toolbars, the following should be taken into account:

- The role is communicated with `role=toolbar`.
- The toolbar should be labeled with `aria-label` or `aria-labelledby`.
- A non-standard vertical orientation of the toolbar can be specified with `aria-orientation=vertical`. Frequently, the orientation is not output by the assistive technology, so that with a vertically oriented toolbar, operation with all arrow keys should be possible.
- The toolbar should also be visually recognizable as such, so that sighted keyboard users are able to recognize the operation with the arrow keys.
- The toolbar should contain at least three control elements.
- The visible elements within the toolbar and the programmatically focused element should have the same position and size.

Further information: [toolbar role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#), [Toolbar Pattern | APG | WAI | W3C](#)

Group

[Online betrachten](#)

Synonyms: Form field group, group field, grouping, groupbox

See also: [Headings](#) , [form](#) , [toolbar](#)

Groups are used to summarise elements that belong together in terms of their content (see DIN EN ISO 9241-161: 8.15). The group has a [label](#) which acts as a group label for the elements it contains.

Practical tip: form field groups in Web applications

Screen reader output

- JAWS: [label] **group** ... **group end**
- NVDA: [label] **grouping** ... **outside of grouping**
- Windows Narrator: -

Please note:

- Form field groups are not output by Windows Narrator.

- In JAWS and NVDA, the end of the form field group is only perceptible with the [virtual cursor](#) when reading. When navigating with TAB, the “group” and/or “grouping” role is only output with the first (and/or with SHIFT+TAB with the last) form element in the group, i.e. when accessing the group. Exiting the group is not perceptible when navigating with TAB. The element overviews of the screen readers display the label of the form field group for each form element in the group.
- For JAWS and NVDA to be able to identify the form field groups, they must be labeled, regardless of whether they are labeled with the HTML element `<fieldset>` or are marked with the ARIA `group` and/or `radiogroup` roles.
- If there is a heading within the `<fieldset>` and outside the `<legend>` element, the group label will not be output correctly by JAWS. Headings should therefore be avoided in `<fieldset>`.

HTML

Form field groups are marked with the `<fieldset>` element and serve the grouping of form fields that belong together, especially in the case of [radio buttons](#). The form elements that belong to the group are nested in the source code within the `<fieldsets>`. The labeling of the form field group takes place with the `<legend>` element which should be the first child element in the `<fieldset>`. As the group label is output before the label of the form elements that it contains, it is necessary to take account of the following:

- The label of the group should be as concise as possible without losing any meaning.
- Form field groups should not be nested within each other.

According to the HTML specification, the `<legend>` element can contain control elements. Sometimes, however, this is not supported by the assistive technology; it is therefore recommended that the label of the form field group is only included in the `<legend>` element in text form. The `<fieldset>` element can be marked as disabled with `disabled`. This means that all the contained form elements are disabled (with the exception of form elements located in the `<legend>` element).

Further information: [4.10.15 The fieldset element - HTML Standard \(whatwg.org\)](#), [4].10.16 The legend element - HTML Standard (whatwg.org)](<https://html.spec.whatwg.org/multipage/form-elements.html#the-legend-element>)

ARIA

If the form field group is not implemented with the HTML element, it is also necessary to take account of the following:

- The role of the list is communicated with `role=group` or `role=radiogroup` (with radio buttons only). When output by screen reader, no distinction is made between the `group` and `radiogroup`.
- The labeling of the group can take place with `aria-label` or `aria-labelledby`.
- The ARIA role `radiogroup` (in contrast to the role `group`) can be marked with the `aria-readonly` attributes as read-only, `aria-required` as a required field and `aria-invalid` as incorrect. In addition to this, `aria-errormessage` can be used to assign an error message to the ARIA radio buttongroup.
- Both the ARIA role `radiogroup` and the ARIA role `group` can be marked with `aria-disabled` as disabled. This means that all the contained form elements are output as disabled by the assistive technology (i.e. they should actually be disabled).

Further information: [group role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)
, [radiogroup role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

List

[Online betrachten](#)

See also: [Selection list](#) , [tree structure](#) , [table](#)

A list is used for the structured display of data. A list contains several list entries. Lists can be sorted or unsorted. Lists can be nested inside each other. Lists often have a visual indicator at the beginning of each list entry, which is also known as a bullet point, e.g.

- a dash or an icon for an unsorted list
- a letter or a number for a sorted list.

List entries can contain control elements.

Unsorted list

- List entry 1
- List entry 2
- List entry 3
- List entry 4
- List entry 5

Practical tip: lists in Web applications

Screen reader output of sorted and unsorted lists

With the [virtual cursor](#) :

- JAWS:
 - **List** with [amount] entries (nesting [level])
 - [Bullet point] [list entry]
 - **List end** (nesting [level])
- NVDA:
 - **List** with [amount] entries
 - [Bullet point] [list entry]
 - **Outside of list**
- Windows Narrator:
 - **Open list**
 - [Position] of [amount] level [level] [bullet point] [list entry]
 - **Close list**

Note: The Windows Narrator incorrectly outputs “heading level [number]“ for each list entry due to the implicit and/or explicit **aria-level**.

HTML

Unsorted lists are marked with `` and ``. For control elements in a list, `<menu>` is also used instead of ``. The `<menu>` element is communicated to the Accessibility API with the semantics of the `` element.

Sorted lists are marked with `` and ``. With sorted lists, it is possible to specify the start value with **start**, change the direction with **reversed**, and determine the type of bullet point with **type**.

Nested lists are implemented such that a list (`` or ``) is located within a `` element of the parent list.

The difference between a sorted list and an unsorted list, i.e., between `` and ``, can only be identified visually and with the assistive technology on the basis of the bullet points. The bullet points should therefore match the list type.

Simple bullet points, such as **disc** for unsorted lists or **decimal** and/or **lower-latin** for sorted lists, should be chosen to ensure the correct output and to avoid lengthening it unnecessarily. The following sample values of the **list-style-type** CSS characteristic are output by the JAWS (first entry), NVDA (second entry, if different), and Windows Narrator (third entry, if different) screen readers as follows:

- **none**: [no output]
- **disc**: Bullet points
- **circle**: round hollow bullet point / white bullet point / empty bullet point
- **square**: black square / large filled black square / [no output]
- **disclosure-open**: black downward pointing small triangle / black downward pointing small triangle / [no output]
- **disclosure-closed**: filled right-pointing small triangle / black right-pointing small triangle / [no output]
- **decimal**: [number]
- **lower-roman**: [number; with numbers that only consist of one letter, just the letter; with numbers that consist of several letters, the individual letters or as a word] / [number; with numbers that consist of several letters, the individual letters] / [number; with numbers that consist of several letters, the letters as a word]
- **lower-latin**: [letter]
- **lower-greek**: [letter with the supplement “Greek lowercase”] / [no output] / [no output]
- **georgian**: [no output]

List characters with **list-style-image** are not output by JAWS and NVDA and are output as an “image” (without alternative text) by Windows Narrator.

Further information: [4.4.5 The ol element - HTML Standard \(whatwg.org\) \(External Link\)](#)
, [4.4.6 The ul element - HTML Standard \(whatwg.org\) \(External Link\)](#)
, [4.4.7 The menu element - HTML Standard \(whatwg.org\) \(External Link\)](#)
, [4.4.8 The li element - HTML Standard \(whatwg.org\) \(External Link\)](#)

ARIA

If the list is not implemented with the HTML element, it is also necessary to take account of the following:

- The role of the list is communicated with **role=list**.
- The role of the list entries is communicated with **role=listitem**.
- Nested lists can be implemented with **aria-level** according to the ARIA specification. This is only output correctly by Windows Narrator, however. For nested lists to be output correctly by JAWS and NVDA, nested lists should be nested correctly in the source code (for example: `<div role=list><div role=listitem>Entry 1<div role=list><div role=listitem>Entry 1.1 ...`).

Further information: [list role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

Table

[Online betrachten](#)

See also: [List](#) , [Hierarchical table](#)

A table is used for the structured display of data (see DIN EN ISO 9241-161: 8.44).

A table consists of cells which are arranged in columns and rows. In most cases, the first row contains the column headings and the first column frequently contains the row headings. Tables can also contain various functionalities, e.g.

- sorting and filtering of the cell contents (e.g. through the column headings),
- scaling of the column and row size,
- showing or hiding of columns and/or changing the order of columns,
- showing and hiding of subordinate table rows (see: Hierarchical table),
- displaying sum total rows at the end of the table,
- in-line editing of cell contents (hereinafter referred to as editing mode),
- external editing of the cell content, e.g. using a [toolbar](#) above the table or a [button](#) within the table cells,
- Selection of table rows, e.g. by [checkbox](#) (multiple selection) or [radio button](#) (single selection),
- Selection of table cells, e.g. by mouse or keyboard selection,
- Browsing or scrolling through the records, if necessary, with [pagination](#) .

The requirements for the individual control elements within the table are described for the respective control element. Only the additional requirements for the whole of the element are described here.

Column heading 1	
Row heading 1	
Row heading 2	
Row heading 3

395	Value	Tables should not have rows or columns that only have empty cells.	Should	EN 301 549: 11.5.2.7
396	Resizing	To make its contents perceptible without horizontal scrolling, no table cell may be wider than 320 px with 400% zoom.	Must	EN 301 549: 9.1.4.10, 11.1.4.10
397	Focus visibility	If a table cell or an element in it receives the keyboard focus, the focus indicator must be visible (see		

Operation

[section separators](#) between the column headings.

Note 2: Alternatively, the control elements outside the table can also be used to enable the table functionality.

Note 3: If keyboard shortcuts are used to enable the use of the keyboard, they must be described in the application and the Help option.

Note 4: The operation of the elements may not conflict with the navigation through the table. If the table can be navigated through with the use of the arrow keys, for example, the table may not contain any control elements that can be operated with the arrow keys unless it is possible to switch to the edit mode.

[Use of the pointing device](#)). | Should | WCAG 2.2 |

No.	Property	Description	Classification	Reference
398	Use of the keyboard	<p>It must be possible to access, operate and exit all control elements in the table with the keyboard (see Use of the keyboard table, below).</p> <p>Note 1: This also applies to functions that can be initialized from the column headings, such as the sorting of the cell contents or the adjusting of the column width through the</p>		

| Must | EN 301 549: 9.2.1.1, 11.2.1.1, 9.2.1.2, 11.2.1.2 | | @!399 | Click area | The click area of the control elements in the table should total at least 24 x 24 px (see

Use of the keyboard: table (in an application that supports the virtual cursor)

With applications that support the virtual cursor, neither the tables nor their cells receive the keyboard focus. It should only be possible for interactive elements within the table cells to be accessed and operated with the keyboard. This only applies if the table is not marked with `role=grid`. Tables with `role=grid` are operated like tables in applications without the virtual cursor (see following section).

Action	Key	Classification
Focusing interactive elements in the table	TAB	Required
Exiting interactive elements in the table	TAB	Required
Operating interactive elements in the table	Corresponding to the respective element	Required

Use of the keyboard: table (in an application that does not support the virtual cursor)

With applications that do not support the [virtual cursor](#) and with tables that have been marked with `role=grid`, each table cell must be able to receive the focus so that its contents are perceptible with the assistive technology (e.g. screen reader). It is not sufficient if it is only possible to navigate through the table only one row at a time, for example. For tables in applications that do not support the virtual cursor, a distinction is made between the navigation and edit mode:

- In the navigation mode, the arrow keys can be used to navigate between the cells.
- In edit mode, the interactive elements within a cell are operable. If the cell contains multiple interactive elements, it is possible to navigate between the elements in the edit mode.

[multiple selection list](#) element.

Action	Key	Classification
Focusing of the table	TAB	Required
Exiting the table	TAB	Required
Cell-based navigation within the table in navigation mode	UP/DOWN/LEFT/RIGHT ARROW	Required

Practical tip: tables in desktop applications

Tables in list form

Some programming languages for desktop applications do not allow for the creation of tables which fulfill the navigation requirements within the table (with the use of the arrow keys). Instead of this, the table can only be navigated one row at a time. Therefore, for example, the table cannot be perceived in a structured way with a screen reader (because the entire row is output, in some cases without the corresponding column headings). In addition, in most cases, the control elements in the table cannot be operated with the keyboard.

In the following exceptional cases, the use of these tables is acceptable if the technology used does not offer an alternative:

- the table only contains two columns or
- the table contains a maximum of five columns and the column headings and cell contents are short (maximum of one to two words or numbers), and

- the column headings are output when navigating through the rows, or the output is not necessary because the purpose of the columns is determined by the context (e.g. the cell content), and
- the rows and column headings do not contain control elements and/or all control elements are perceptible with assistive technology (role, purpose, status) and are operable with the keyboard and/or assistive technology.

If these requirements cannot be met, a different form of presentation must be chosen for the data.

Interactive elements in the table

Some programming languages for software do not allow for the creation of tables which fulfill the requirements referred to here regarding the operation of interactive elements within tables. In this case, interactive elements within the tables should be avoided. Instead of this, the tables should only be used to display data and the associated interactive elements should be located outside the table. Examples:

- One or more control elements can be inserted in front of the table to manage the sorting of the table contents.
- A form can be inserted above the table to filter the table contents.
- Above the table, a [button](#) can be added with which a [modal dialog](#) can be opened. In the modal dialog, the table can be fully configured using the keyboard (by adjusting the column widths, for instance).
- Above the table, there is a [toolbar](#) with which the selected table rows can be edited or deleted.

Alternatively, [keyboard shortcuts](#) or [context menus](#) can be used to enable the use of the keyboard. In this case, this alternative form of operation must be referred to in the application and the [Help](#) option.

With the control elements in the table that may be inaccessible, another option is to ensure the accessible operation with the use of control elements outside the table.

Hierarchical table

[Online betrachten](#)

Synonyms: Table with tree structure, tree grid, tree table

See also: [Table](#) , [tree structure](#) , [accordion](#)

A hierarchical table is designed to display hierarchical data in columns and rows in a structured way, in which subordinate data can be displayed and hidden row by row. An indicator on the rows shows whether the subordinate rows are shown or hidden.

In most cases, the first row contains the column headings and the first column frequently contains the row headings. Hierarchical tables can contain interactive elements, such as [buttons](#) for performing an action or [check boxes](#) for selecting a table row.

Figure 24: Hierarchical table

Presentation

The requirements regarding the table are described in the “table” section. Here, only the additional requirements are described which result from the ability to show and hide subordinate rows in the table.

No.	Property	Description	Classification	Reference
454	Contrast	Icons that display the status of table rows (shown or hidden) must have a contrast ratio of at least 3:1 with respect to the background.	Must	EN 301 549: 9.1.4.11, 11.1.4.11

Operation

Title bar

[Online betrachten](#)

Synonyms: Title

See also: [Heading](#) , [status bar](#)

The title bar is the top element of the application window and contains the title (see DIN EN ISO 9241-161: 8.47).

The text in the title bar is usually one-line. The title bar can contain an application icon. The title of the window is also displayed by the icons in the task bar or by pressing ALT+TAB when switching between the applications. The title bar often contains interactive elements (for closing, scaling, and minimizing the application) which are not in the tab loop.

Only those requirements that are directly related to the title bar are described below. Requirements of elements within the title bar are described at the respective element.

Note: Most of the requirements concerning the title bar refer to desktop applications only. For Web applications, the browser is the window with the title bar. The Web application itself does not contain a title bar. The labeling of the title bar of the browser is defined using the `<title>` element, however.

Title

<p>Note: Important status messages are error messages, for instance. A status message about the amount of characters entered is considered unimportant in a word processing system, especially as this changes constantly following the input.</p> Must EN 301 549: 11.4.1.3.1				

Modal dialog

[Online betrachten](#)

Synonyms: Dialog window, message, pop-up, dialog, dialog box

See also: [Window](#) , [tooltip](#) , [error message](#)

A modal dialog is used to display important information and control elements in a separate area. A modal dialog blocks the operation of the application window in the background (see DIN EN ISO 9241-161: 8.10).

A modal dialog always contains a text and one or more buttons that can be used to close the dialog. The modal dialog can also contain a [title bar](#) and [status bar](#) as well as other control elements, graphics, etc.

The requirements regarding the content of the modal dialog are described at the respective element. Only specific requirements for modal dialog are described here.

Examples:

A diagram illustrating the structure of a modal dialog. It shows a dark gray rounded rectangle representing the dialog box. The top part is a dark gray bar labeled "Title bar". Below the title bar, the dialog is divided into two rows: "Row 1" and "Row 2".

Section separator

[Online betrachten](#)

Synonyms: Separator, window splitter, splitter

See also: [Control point](#) , [slider](#) , [scrollbar](#)

A section separator is used to scale a page area or two neighboring page areas. Section separators are also used to scale table columns and rows.

A section separator is located between two page areas and consists of a bar and in some cases a control point. Section separators can have different manifestations:

- arranged horizontally or vertically,
- continuous or incremental scaling,
- scaling in the range of 0 to 100% (i.e., between hidden and full screen), or with a restricted area,
- scaling of both areas or only one of the two areas (the other area then moves, but remains unchanged in its size).

Figure 28: Section separator

[Accessibility API](#)). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!476 | Status | The status of the link must be communicated to the Accessibility API (see

[Element status](#)).

provided that this information is communicated in visual form.

Note: If the Accessible Name is not expressive, the programmatically perceptible link context can also be used to communicate the purpose of the link.

[Focus indicator](#)). | Must | EN 301 549: 11.5.2.5, 11.5.2.13 |

No.	Property	Description	Classification	Reference
475	Role	The role of the link must be communicated to the Accessibility API (see		

Note: This also applies to information

- about the linked document format (e.g. PDF),

No.	Property	Description	Classification	Reference
		<ul style="list-style-type: none"> • about the link destination (e.g. internal or external links), • about the link type (e.g. link to a phone number or email address), • about the position in the application (for example, link to the current page), 		

Practical tip: links in Web applications

Screen reader output

- JAWS: [label] **link** | link this page | visited link | send link email | FTP link
- NVDA: [label] **link** | visits link
- Windows Narrator: **link** [label] value [URL]

Note:

- JAWS and NVDA distinguish between visited and unvisited links.
- With JAWS, the link type of some links is perceptible (link to email and FTP addresses, page-internal links).
- With Windows Narrator, the link type is perceptible on most links, as the URL is output as the value of the link. The output of the URL is not correct, however, which means that “http://” is output as “http skeptical smiley”.

HTML

The link should be implemented with the HTML element ``. The `href` attribute is required.

Label:

- The labeling of the link should take place using the text content.
- In the case of graphic links, the labeling takes place using the alternative text of the graphic or `aria-label`. It should be noted that the link label does not describe the graphic, but the purpose of the link. If the content of the graphic is also relevant, the graphic should not be linked, but the link should be located before or after the graphic.
- The labeling of the links should be concise. For example: In the case of a tile with a heading, graphic, teaser text, keywords, etc., it is not necessary for the entire tile to be linked, but just the heading.
- The labeling of the links should be unambiguous and expressive. Links labeled “Click here” or “Further information” are not considered expressive. The label should either be expressive (e.g. “Further information on accessibility”), or the description should explain the purpose of the link (by referring to the relevant context of the link with `aria-describedby`, for example).

Status and type:

- Links cannot be marked as disabled (`disabled`). Links which are not operable can be marked with the `<a>` element without the `href` attribute.
- In the case of links that are used for page navigation, `aria-current=page` can be used to mark the link that refers to the current page.
- Links that are used to show and hide areas should be marked with `aria-expanded` to communicate the status of the areas (shown or hidden).
- Links that open with a pop-up should be marked with `aria-haspopup`.
- Unless the link opens a new Web page in the current browser window, a visual reference should be made to the deviating link destination (e.g. the link opens a page in the new browser window, the link refers to a PDF document).
- If the links have a graphic reference that refers to the type of link (e.g. link to an external page, link opens a page in the new browser window, link refers to a PDF document, linked email address), this information should also be perceptible with assistive technology. The type of link is generally a secondary piece of information, which means that it should not be output as part of the label, but as a description (e.g. using `title` or `aria-describedby` attribute), or at least only at the end of the label.

Further information: [4.6 Links - HTML Standard \(whatwg.org\) \(External Link\)](#)

ARIA

If the link is not implemented with the HTML element, in addition to the notes on HTML links, it is necessary to take account of the following:

- The role is communicated with `role=link`.
- Disabled links can be marked with `aria-disabled`.

- The communication of the information that a link has already been visited or that it consists of a page-internal link is not possible with ARIA links.
- The links should be visually marked (with an icon or underline, for example) so that their role is also perceptible when using Windows Contrast Adjustment.

Note: The Accessible Name of a button cannot, therefore, be simply “Close” or “Delete” if only the visual context indicates which element is closed or deleted. Instead, the Accessible Name must be “Close pop-up” or “Delete file [file name]”, for instance. Alternatively, the Accessible Description must contain a reference to the element which is to be closed or deleted.

| Must | EN 301 549: 9.1.3.1, 11.1.3.1, 9.2.4.6, 11.2.4.6, 9.3.3.2, 11.3.3.2 | | @!504 | Keyboard shortcut | If the button has a visually perceptible keyboard shortcut, it must be communicated to the Accessibility API. | Must | EN 301 549: 9.1.3.1, 11.1.3.1 | | @!505 | Operation | It must be possible to access, operate and exit the button with assistive technology (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.12, 11.5.2.17 | | @!506 | Update | Updates concerning the Accessible Name or status of the button must be communicated to the Accessibility API (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.15 | | @!507 | Desktop: Position | The size and position of the button must be communicated to the Accessibility API (see

Practical tip: buttons in Web applications

Screen reader output

- JAWS: [label] **button** [note on operation with the Enter key]
- NVDA: [label] **button** | graphics button
- Windows Narrator: [label] **button**

Please note:

- The type of button (**type=reset**, **type=submit**, **type=button**) is not perceptible with the screen readers.

- Only NVDA outputs the element `<input type=image>` as a “graphic button”.

HTML

The button should be implemented with the HTML elements `<button>` or `<input type=button>`. For graphic buttons, `<input type=image>` can be used. In forms, `<input type=submit>` and/or `<input type=reset>` can be used for the buttons for sending and resetting the inputs.

Label:

- The labeling of the buttons that are labeled with `<button>` should take place using the text content.
- The labeling of the buttons that are labeled with `<input>` should take place using the `value` attribute.
- Buttons that are labeled with `<input type=submit>` or `<input type=reset>` do not need to be explicitly labeled because they are labeled automatically by the browser (with “Send” and “Reset”, for instance). The default labeling of the browser can be overridden with the `value` attribute, however. This is recommended if reference is made to these buttons in the application or the Help option, because the label of the buttons is otherwise different according to the browser.
- In the case of graphic buttons, the labeling takes place using the alternative text of the graphic (e. g. `<input type=image alt=...>` and/or `<button></button>`) or with `aria-label`. It should be noted that the button label does not describe the graphic, but the purpose of the button.
- The labeling of the buttons should be concise, unambiguous and expressive. Buttons labeled “Click here” or “Detailed view” are not considered expressive. The label should either be expressive (e.g. “Detailed view of Joe Bloggs”), or the description should explain the purpose of the button (with `aria-describedby` or `title`, for example).

Status and type:

- Buttons can be marked as disabled (`disabled`).
- With buttons that are used for navigation or pagination, `aria-current` can be used to mark the button which refers to the current element.
- Buttons that are used to show and hide areas should be marked with `aria-expanded` to communicate the status of the areas (shown or hidden).
- Buttons that open a pop-up should not be labeled `aria-haspopup`, even if the attribute is intended for that purpose. This is because, when combined with a button, `aria-haspopup` causes the element to be output as a [menu button](#). Instead, links should be used with `aria-haspopup` r buttons that have a text note in the description.

Further information: [4.10.6 The button element - HTML Standard \(whatwg.org\)](#), [4.10.5.121 Button state \(type=button\) - HTML Standard \(whatwg.org\)](#), [4.10.5.119 Image Button state \(type=image\) - HTML Standard \(whatwg.org\)](#), [4.10.5.118 Submit Button state \(type=submit\) - HTML Standard \(whatwg.org\)](#), [4.10.5.120 Reset Button state \(type=reset\) - HTML Standard \(whatwg.org\)](#)

ARIA

If the button is not implemented with the HTML element, in addition to the notes on HTML buttons, it is necessary to take account of the following:

- The role is communicated with `role=button`.
- Disabled buttons can be marked with `aria-disabled`.
- The buttons should be visually marked (with a border, for example) so that their role is also perceptible with the use of Windows Contrast Adjustment.

Further information: [button role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\)](#), [Button Pattern | APG | WAI | W3C](#)

Switch

[Online betrachten](#)

Synonyms: Switch button, toggle switch

See also: [Button](#) , [check box](#) , [menu switch](#) , [toggle switch](#)

A switch is used to select the values “On” or “Off”. The switch can also be used for other value pairs, provided that these values are communicated in text form.

A switch has a border that contains a visual indicator which displays the selected value on the basis of its position. The indicator is usually a circle which is positioned on the left (“Off” value) or right (“On” value) in the border.

Figure 31: Switch in the On and Off state

Presentation

The requirements concerning buttons are described in the “buttons” section. Here, only the additional requirements are described which result from the fact that it is a button that is able to have two states.

No.	Property	Description	Classification	Reference
508	Contrast	The visual indicator for the value must have a contrast ratio of at least 3:1 with respect to the background.	Must	EN 301 549: 9.1.4.11, 11.1.4.11
509	Contrast	If the value of the switch is also communicated in text form, it must have a contrast ratio of at least 4.5:1 with respect to the background.	Must	EN 301 549: 9.1.4.3, 11.1.4.3
510	Value	The value of the switch should also be communicated in text form. Note: Although “On” is associated with the right position and “Off” is associated with the left position, it cannot be assumed that all users are familiar with this. In addition, the value is often color coded (“On” in green or a dark color, “Off” in red or a light color). The colors may not be perceivable by people who are disabled, however.	Should	DIN EN ISO 9241-143: 9.6.11

Operation

The requirements concerning buttons are described in the “buttons” section. Here, only the additional requirements are described which result from the fact that it is a button that is able to have two states.

Programming/interfaces

The requirements concerning buttons are described in the “buttons” section. Here, only the additional requirements are described which result from the fact that it is a button that is able to have two states.

[Accessibility API](#). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!513 | Value | The value of the switch must be communicated to the Accessibility API (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.7 | | @!514 | Value | If the values of the switch do not represent “On” and “Off”, but are used for other states which are visible in text form on the switch, these values must be communicated to the Accessibility API. | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.7 |

No.	Property	Description	Classification	Reference
512	Role	The switch role must be communicated to the Accessibility API (see		

Practical tip: switches in Web applications

Screen reader output

- JAWS: [label] **toggle switch** [off | pressed on]
- NVDA: [label] **control panel** [not enabled | enabled]
- Windows Narrator: [label] **button** [off | on]

Note:

- Although there is an individual role for switches with `role=switch`, it is not output by the screen readers. Instead, the switches are output as [toggle switches](#) and/or [check boxes](#). This is not problematic, as the functionality is analog.
- The only problem is that the value in text form (if present) is imperceptible with the screen reader.

HTML

There is no element for switches in HTML. Toggle switches or check boxes can be used instead.

ARIA

In this respect, with switches, the following should be taken into account:

- The role is communicated with `role=switch`.
- The status is communicated with `aria-checked=true/false` and must be updated during operation.
- The labeling can take place by text content or `aria-labelledby`.
- The switch can be marked as read-only with `aria-readonly` and as disabled with `aria-disabled`.

- A switch can be marked as a required field with `aria-required`. This is only useful in cases where the switch has to be submitted in the “On” status (`aria-checked=true`). However, if at least one switch in a group of switches must be selected, the required field label should be carried out with the group (e.g. asterisk within the group label).
- The status of the switch should be displayed in text form, as color information (such as green = on and red = off) may be imperceptible for visually impaired people.
- The switch should only be used for the “on” and “off” status, because other status information is not communicated by the screen reader. Alternatively, other status information should be communicated as part of the label or description. In this case, however, it should be noted that the programmatic status is also output, which leads to a redundant output.
- The presentation of the switch should be verified in Windows High Contrast mode. The switch itself, for example, and the visual indicator of the status should have a border and not just be marked with background color.
- The visible switch and the programmatically focused element should have the same position and size.

Further information: [switch role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#), [Switch Pattern | APG | WAI | W3C](#)

Toggle switch

[Online betrachten](#)

Synonyms: Toggle button

See also: [Button](#) , [check box](#) , [menu button](#) , [switch](#)

Toggle switches are used to select the “pressed” or “not pressed” states (see DIN EN ISO 9241-161: 8.48).

A toggle switch consists of a text or graphic label and a visual indicator in order to identify the toggle switch as such. A border is usually used as a visual indicator for toggle switches. The toggle switch also has a visual indicator of the state, such as a different background color.

Figure 32: Toggle switch in the pressed and not pressed status

Presentation

[Accessibility API](#)). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!518 | Status | The status of the toggle switch must be communicated to the Accessibility API (see

[Element status](#)).

No.	Property	Description	Classification	Reference
517	Role	The toggle switch role must be communicated to the Accessibility API (see		
<p>Note: This also applies to the “pressed” or “not pressed” status.</p> <p> Must EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 </p>				

Practical tip: toggle switch in Web applications

Screen reader output for toggle switch with aria-pressed

- JAWS: [label] **toggle switch** [| pressed] [note on operation with the Space bar]
- NVDA: [label] **toggle switch** [not pressed | pressed]
- Windows Narrator: [label] **button** [off | on]

Screen reader output for toggle switch with aria-expanded

- JAWS: [label] **button** [reduced | expanded] [note on operation with the Enter key]
- NVDA: [label] **button** [reduced | expanded]
- Windows Narrator: [label] **button** [hidden | expanded]

HTML

There is no element for toggle switches in HTML. Instead of this, [buttons](#) that have alternative labeling (e.g. “Select” and/or “Cancel selection”), [check boxes](#) or the ARIA toggle switch can be used. Toggle switches which have the purpose of showing and hiding areas should be marked with `<details>` and `<summary>` ([4.11.1 The details element - HTML Standard \(whatwg.org\) \(External Link\)](#)

, [4.11.2 The summary element - HTML Standard \(whatwg.org\) \(External Link\)](#)

). According to the HTML specification, the `<summary>` element may contain links, headings, input fields and many other elements – it is important to remember, however, that all the elements which are located within `<summary>` are imperceptible and cannot be operated with the screen reader, as the `<summary>` element is communicated to the Accessibility API as a button. Therefore, the `<summary>` element should only contain a concise and expressive label in text form.

ARIA

With toggle switches, the following should be taken into account:

- with a button (e.g. `<button>` or `role=button`), the role is communicated with the `aria-pressed` attribute.
- toggle switches that have the purpose of showing and hiding areas can instead be marked with the `aria-expanded` attribute. In this case, `aria-controls` can be used to make reference to the ID of the area that is shown or hidden.

- The status (`aria-pressed=true|false` or `aria-expanded=true|false`) must be updated during operation.
- The labeling can take place using text content or `aria-labelledby`.
- The toggle switch can be marked as disabled with `aria-disabled`.
- A toggle switch cannot be marked as read-only with `aria-readonly` or as a required field with `aria-required` because, in contrast to a [switch](#) , it is not considered to be a form element.
- The presentation of the toggle switch should be verified in Windows High Contrast mode. In this respect, the toggle switch should have a border and the visual indicator for the status should not just be conveyed with color.
- The visible toggle switch and the programmatically focused element should have the same position and size.

Split button

[Online betrachten](#)

Synonyms: Bifurcated switch

See also: [Drop-down list](#) , [menu button](#) , [context menu](#) , [button](#)

Split buttons are for the execution of a command that can be configured using a [menu](#) , a [selection list](#) or a [dialog window](#) .

Alternatively, split buttons are used for grouping related functions, where the primary function can be initialized directly using the button and the secondary functions can be initialized using the menu at the button.

A split button consists of a text or graphic label and a visual indicator in order to identify the button as such (usually a border). The split button also has additional buttons (with arrow icon), with which the secondary functions can be shown and hidden.

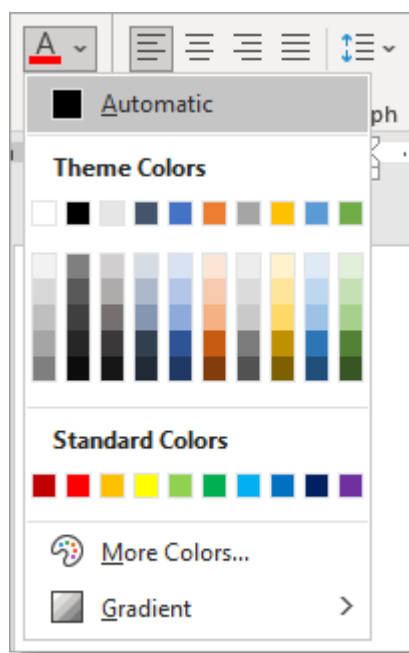

Figure 33: Split button for the selection of a color

Presentation

The requirements concerning buttons are described in the “buttons” section. Here, only the additional requirements are described which result from the fact that it is a button with primary and secondary functions. The requirements regarding the elements that can be shown are described at the respective element.

No.	Property	Description	Classification	Reference
519	Contrast	The arrow icon for opening and closing the menu or similar must have a contrast ratio of at least 3:1 with respect to the neighboring color.	Must	EN 301 549: 9.1.4.11, 11.1.4.11

No.	Property	Description	Classification	Reference
520	Contrast	<p>If the selected entry only differs from the unselected entry in the open state due to its color (e.g. foreground or background color), the colors must have a contrast ratio of at least 3:1.</p> <p>Note: The selected entry does not have to be color coded or marked with color only. It can be marked with a check box, for example. In this case, the contrast requirements for the color coding are eliminated as long as the check box has sufficient contrasts.</p>	Must	EN 301 549: 9.1.4.11, 11.1.4.11

Operation

The requirements concerning buttons are described in the “buttons” section. Here, only the additional requirements are described which result from the fact that it is a button with primary and secondary functions. The requirements regarding the elements that can be shown are described at the respective element.

<p>Note: If this is not possible, the value must be communicated as part of the label or description.</p> <p> Must EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 </p>				

Practical tip: split buttons in Web applications

HTML

There is no element for split buttons in HTML. Instead, two [buttons](#) with expressive labeling (e.g. “Assign text color” and/or “Select text color”) can be used which receive the focus with TAB.

ARIA

There is no role for split buttons in ARIA. Instead, two separate buttons can be used as described above.

Context menu

[Online betrachten](#)

Synonyms: Pop-up menu, pie menu

See also: [Menu button](#) , [menu](#)

Context menus are used for displaying a context-specific menu with function for the element currently focused with the keyboard or moved over with the pointing device (see DIN EN ISO 9241-161: 8.29).

A context menu has one or more menu items which are mostly vertical. A menu item can have a sub-menu. The menu items of a sub-menu are also arranged vertically. Sub-menus can also be nested several times, i.e. a menu item in a sub-menu can also have a sub-menu.

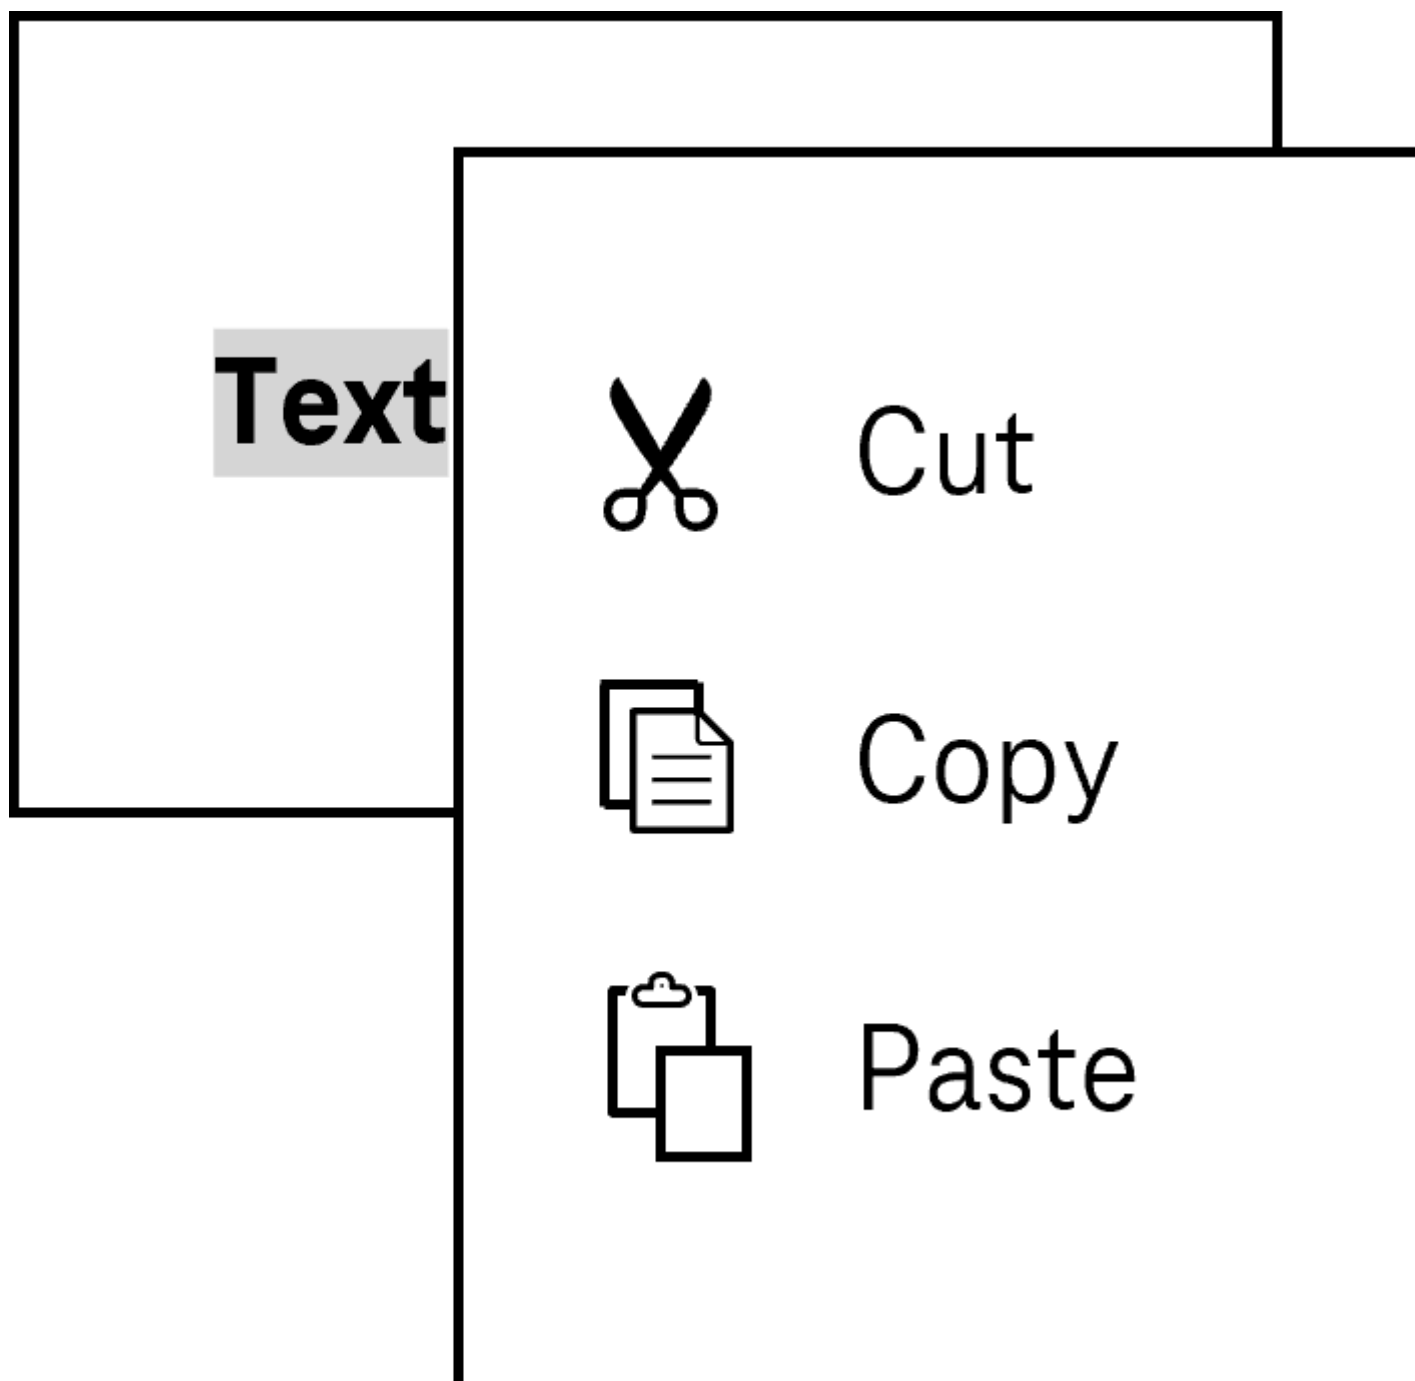

Figure 34: Context menu for the text editing

Presentation

The requirements concerning the menu are described in the “menu” section. Here, only the additional requirements are described which result from the fact that it is a context menu.

No.	Property	Description	Classification	Reference
524	Contrast	If the control element with context menu has a visual reference to the context menu, this must have a contrast ratio of at least 4.5:1 (text) and/or 3:1 (graphic) with respect to the background.	Must	EN 301 549: 9.1.4.3, 11.1.4.3, 9.1.4.11, 11.1.4.11

Operation

Practical tip: tab groups in Web applications

Screen reader output for tab panel

- JAWS: [label of the tab bar] **tab** [label of the tab panel] tab [| selected] [position] of [amount]
- NVDA: [label of the tab bar] **tab** [label of the tab panel] tab [| selected] [position] of [amount]
- Windows Narrator: [label of the tab bar] **tab** [label of the tab panel] **tab element** [position] of [amount] [| selected]

Note: JAWS and NVDA output “tab” twice, first for the **tablist** role and then for the **tab** role. Only Windows Narrator distinguishes between the two roles. The output for the **tab** role would be sufficient.

Screen reader output for tabs

- JAWS: -
- NVDA: -
- Windows Narrator: [label] **tab panel ... end** [label] tab panel

Note: With JAWS and NVDA, the start and end of the tab is not perceptible. The tabs or content after this should be labeled as regions, so that which specific content is located inside and outside the tabs is perceptible with the screen reader.

HTML

There is no element for tab groups in HTML. Instead, the following can be used:

- Allocation of the information to different pages that are linked with each other,
- [Accordion](#) ,
- Use of the corresponding ARIA roles.

ARIA

With tab groups, the following should be taken into account:

- The tab panel bar is marked with `role=tablist`, while the individual tab panels that are located inside the bar as child elements are marked with `role=tab`.
- The tab panel bar may not contain any elements apart from the tab panels.
- If the tab panels contain other control elements besides their labeling, it should be noted that these are imperceptible and not operable with the assistive technology. These elements should not be able to receive the keyboard focus. An alternative form of operation should be implemented and documented instead. If the tab panels contain a button for removing a tab, it is possible for the deletion to be enabled with the DELETE key.
- The tab panels are marked with `role=tabpanel`. The tabs are located in the source code immediately after the area which is marked with `role=tablist`. Due to this and the preceding reason, a tab group may not be used for accordions.
- The active tab panel, the tab of which is visible and which receives the focus with TAB, is marked with `aria-selected=true`. All of the other tab panels are marked with `aria-selected=false`. Reference can be made to the ID of the tab from the tab panel using `aria-controls`.
- The labeling of the tab panels should take place using text content. The bar of the tab panels and tabs can be labeled with `aria-label` or `aria-labelledby`.
- A non-standard vertical orientation of the tab bar can be specified with `aria-orientation=vertical`. Frequently, the orientation is not output by the assistive technology, so that with a vertically oriented tab bar, operation with all arrow keys should be possible.
- The tab bar should also be visually recognizable as such, so that sighted keyboard users are able to recognize the operation with the arrow keys.
- The tab group should contain at least two tabs.
- The tab panels can be marked as disabled with `aria-disabled`. It is recommended that disabled tab panels are left in the keyboard accessibility with the arrow keys.
- The selected tab (`role=tabpanel`) can be marked as `tabindex=0` so that it receives the focus after the active tab panel, even if a specific tab is not a control element.
- The presentation of the tab group should be verified in Windows High Contrast mode. In this respect, the tab panels and tabs should have a border and the visual indicator for the active tab panel should not just be conveyed with color.

- The visible tab panels and the programmatically focused elements should have the same position and size.

Practical tip: one-line input field in Web applications

Screen reader output

- JAWS: [label] **input field** [value] [instruction on text input]
- NVDA: [label] **input field** [value]
- Windows Narrator: [label] **edit** [value]

HTML

The input field should be implemented with the HTML element `<input type=text>`. For an input field which is used for entering search terms, `<input type=search>` can be used. The screen readers output the search field as a normal input field, i.e. the label must indicate the purpose which is the search. The initial value is communicated through the `value` attribute. The label of the input field should be linked to the input field with the `<label for=ID>` element. The maximum and minimum required length of the value can be determined with

maxlength and **minlength**. Neither of the values are perceptible visually or with the use of assistive technology. If they are used, a corresponding instruction should be provided at the input field. If a particular input format is required, instead of `<input type=text>`, the following elements can be used:

- `<input type=tel>` for telephone numbers,
- `<input type=email>` for email addresses,
- `<input type=url>` for Internet addresses,
- `<input type=text pattern=...>` or inputs that must correspond to the regular expression in the **pattern** attribute,
- `<input type=number>` for numbers (see [Spin button](#)),
- `<input type=date>`, `<input type=time>` etc. for date and time information (see [Date picker](#)).

These input fields with a predefined format are automatically validated by the browser. The error messages of the browsers, however, are not accessible, and should therefore be replaced or supplemented with specific error messages from the application (see also: Browser validation of the **required** required attribute in [Practical tip: programmatic label of required fields in Web applications](#)).

The input fields for telephone numbers, email and Internet addresses as well as input fields with the **pattern** attribute are not identifiable either visually or with assistive technology – they are displayed as normal input fields and/or output by the screen reader. They must therefore be labeled in an expressive way and should also have operating instructions for the required input format.

The **inputmode** attribute can be used to specify which virtual keyboard should be displayed on mobile devices because corresponding details are expected (e.g. inputting of numbers, text, URLs, email addresses). The use of **inputmode** does not result in an automatic browser validation. Insofar as the keyboard that is used does not result from the **type** attribute of the input field, the use of **inputmode** is recommended, as assistive technology is also able to use this information appropriately, to display corresponding virtual keyboards, for example. It should be noted that the **inputmode** attribute replaces unnecessary input instructions, however.

The **placeholder** attribute can be used for a placeholder. However, it is recommended to display input instructions next to the field and to link them to the input field using **aria-describedby**. The **placeholder** attribute has the following disadvantages:

- The contrasts are often insufficient (in respect to either the background or the text in the input field, which makes it difficult to distinguish between the placeholder and the value).
- The placeholder is not displayed as soon as the field contains a value.

An input field can be marked as disabled (**disabled**) and read-only (**readonly**).

An input field can be marked as a required field with **required**.

Further information: [4.10.5 The input element - HTML Standard \(whatwg.org\)](#)

ARIA

If the input field is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with **role=textbox**.

- For an input field which is used for entering search terms, `role=searchbox` can be used. The screen readers output the search field as a normal input field, i.e. the label must indicate the purpose which is the search.
- The labeling of the input field can take place with `aria-label` or `aria-labelledby`.
- The value of the input field is derived from the text content of the element which is marked with `role=textbox`.
- The input field can be marked as a required field with `aria-required`, as disabled with `aria-disabled`, and as read-only with `aria-readonly`.
- For a placeholder, `aria-placeholder` is used.
- The presentation of the input field should be verified in Windows High Contrast mode.
- The visible input field and the programmatically focused element should have the same position and size.

Further information: [textbox role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

Input field (multi-line)

[Online betrachten](#)

Synonyms: Text field, text area, multi-line text input, multiline plain text edit control

See also: [Input field \(one-line\)](#) , Rich Text Editor

Multi-line input fields allow for the input of long text contents (see DIN EN ISO 9241-161: 8.45).

A multi-line input field is usually a rectangular area of the page that contrasts with the background due to a border, for example. The border can have a [control point](#) for the scaling of the input field. A multi-line input field can have [scrollbars](#) . The requirements of the control point and scrollbars are described in the appropriate sections.

Label*:

Figure 39: Multi-line input field with top label

 | @!610 | Update | Updates concerning the Accessible Name, value or status of the multi-line input field must be communicated to the Accessibility API (see Accessibility API).| Must | 9.4.1.2, 11.4.1.2, 11.5.2.12, 11.5.2.17 |

Practical tip: multi-line input field in Web applications

Screen reader output

- JAWS: [label] **input field** [instruction on contained value] [instruction on text input]
- NVDA: [label] **multi-line input field** [contents of the current line]
- Windows Narrator: [label] **edit** [value]

Please note:

- With JAWS, the value of the input field is imperceptible when focusing with TAB. The content is only output line by line when navigating through the field.
- With NVDA, the value of the input field is only partially perceptible when focusing with TAB, because only the current line is output. The content is only output line by line when navigating through the field.
- If the input field is empty, with JAWS and Windows Narrator, the difference between a one-line and multi-line input field is imperceptible.
- If the value of the input field contains empty lines and the text cursor is in an empty line, when focusing with TAB with NVDA, it is imperceptible that the input field contains a value because “empty” is output only.

HTML

Note: Multi-line input fields should only be used if very long inputs are expected or if the inputting of paragraph breaks (ENTER key) must be enabled. Otherwise, a one-line input field should be used, because the accessibility of the multi-line input fields is poorer for users of screen readers.

The input field should be implemented with the HTML element `<textarea>`.

The initial value is communicated through the text content of the element.

The label of the input field should be linked to the input field with the `<label for=ID>` element.

The maximum and minimum required length of the value can be determined with `maxlength` and `minlength`.

Neither of the values are perceptible visually or with the use of assistive technology. If they are used, a corresponding instruction should be provided at the input field.

The visual size of the input field can be set using the `cols` and `rows` attributes. It is recommended that the size is defined using CSS instead, so that the multi-line input field can be responsively designed to avoid horizontal scrolling at a screen width of 320 px. The initial size of the input field should be sufficiently large, as keyboard users are not able to change the size of the field – the control point automatically displayed by the browser can only be operated with a pointing device.

The `placeholder` attribute can be used for a placeholder. However, it is recommended to display input instructions next to the field and to link them to the input field using `aria-describedby`. The `placeholder` attribute has the following disadvantages:

- The contrasts are often insufficient (in respect to either the background or the text in the input field, which makes it difficult to distinguish between the placeholder and the value).
- The placeholder is not displayed as soon as the field contains a value.

An input field can be marked as disabled (`disabled`) and read-only (`readonly`). An input field can be marked as a required field with `required`.

Further information: [4.10.11 The textarea element - HTML Standard \(whatwg.org\)](#)

ARIA

If the input field is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=textbox` and the ARIA attribute `aria-multiline=true`.
- The labeling of the input field can take place with `aria-label` or `aria-labelledby`.
- The value of the input field is derived from the text content of the element which is marked with `role=textbox`.
- The input field can be marked as a required field with `aria-required`, as disabled with `aria-disabled`, and as read-only with `aria-readonly`.
- For a placeholder, `aria-placeholder` is used.
- The presentation of the input field should be verified in Windows High Contrast mode.
- The visible input field and the programmatically focused element should have the same position and size.

Further information: [textbox role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#)

Password input field

[Online betrachten](#)

Synonyms: Password field

See also: [Input field \(one-line\)](#) , [authentication](#)

Password input fields allow for the entry of a password.

A password input field is usually a rectangular area of the page that contrasts with its surroundings due to a border, a line or a different background color, for example. The entered value is only displayed in a masked format. A password input field can contain a button to unmask the value.

Enter password:

Figure 40: Password input field

Presentation

The requirements concerning the input field are described in the “input field” section. Here, only the additional requirements are described which result from the fact that it is an input field for entering a password.

Practical tip: password input field in Web applications

Screenreader output

- JAWS: [label] **input field for passwords** [masked value] [instruction on text input]
- NVDA: [label] **protected input field** [masked value]
- Windows Narrator: [label] **edit** [value]

Please note:

- With Windows Narrator, the difference between an input field and a password input field is not perceptible.
- When entered, the masked value, the “black dot” (●) is output as “asterisk” (JAWS, NVDA) and/or “hidden” (Windows Narrator). A value that has already been entered is output as a sequence of “bullet points”, whereby JAWS shortens the amount of characters to three by default.

HTML

To prevent the entered password from being output by the assistive technology, the password input field must be implemented with the HTML element `<input type=password>`.

The label of the password input field should be linked to the password input field with the `<label for=ID>` element.

A password input field can be marked as disabled (`disabled`) and read-only (`readonly`). A password input field can be marked as a required field with `required`.

If specific rules apply when assigning the password, the following should be observed:

- The rules should be explained at the password input field.
- If the rules are short and unstructured, the password input field should be programmatically linked with the rules (with `aria-describedby`, for example).
- If the rules are long or structured, they should be placed in the source code before the password input field, to ensure that the reading sequence is correct. The rules can be given a heading (e.g. “Instructions on password entry”). At the input field, the Accessible Description should make reference to the fact that rules are available (e.g. “Note the input instructions for passwords before this field”).
- If the rules are validated automatically upon input, this should also be perceptible when using assistive technology, e.g. by marking the result of the validation as a live region.

Further information: [4.10.5.1.6 Password state \(type=password\) - HTML Standard \(whatwg.org\)](#)

ARIA

There is no role for password input fields in ARIA. Instead, the appropriate HTML element must be used for password input fields so that the password to be entered is not output by the assistive technology.

Input field with autocomplete function

[Online betrachten](#)

Synonyms: Input field with suggestion list, autocomplete search, auto suggestion box

See also: [selection list](#) , [drop-down list](#) , [menu button](#) , [input field \(one-line\)](#) , [combined input field](#)

Input fields with the autocomplete function allow for text to be entered freely and the selection of options from a list, whereby the list is only opened after the text has been input.

In the closed state, an input field with autocomplete function consists of a single input field. In the opened state, a [selection list](#) is displayed underneath (possibly with a [scrollbar](#)). The options of the selection list can be grouped. The labeling of the groups cannot be selected.

Input fields with the autocomplete function can also add the first hit to the input field automatically, so that this can be adopted immediately (Inline-Autocomplete). In this case, the text cursor remains at the position of the last character entered.

Practical tip: spin button in Web applications

Screen reader output

- JAWS: [label] **spin button** [value] [instruction on text input and operation with the arrow keys]
- NVDA: [label] **spin button** | spin button editable [value]
- Windows Narrator: [label] **net** | **spin button** [value] minimum [minimum value] and maximum [maximum value]

Please note:

- The Windows Narrator outputs the HTML spin buttons as a “net” and the ARIA spin buttons as a “spin button”.
- The minimum and maximum values are only perceptible with the Windows Narrator.
- The difference between spin buttons with and without text input is only perceptible with NVDA.

HTML

The spin button should be implemented with the HTML element `<input type=number>` The initial value is communicated through the `value` attribute

The increment as well as the minimum and maximum values can be communicated with the `step`, `min` und `max` attributes.

The label of the spin button should be linked to the spin button with the `<label for=ID>` element.

A spin button can be marked as disabled (`disabled`) and read-only (`readonly`) ausgezeichnet werden. A spin button can be marked as a required field with `required`.

Further information: [4.10.5.1.12 Number state \(type=number\) - HTML Standard \(whatwg.org\)](#)

ARIA

Please note: On mobile devices, an ARIA spin button without text input may not be operated with assistive technology, because no gesture commands for the operation of non-native spin buttons have been implemented. This applies, in particular, if the buttons for increasing and/or decreasing the value are child elements of the spin button. In addition to this, the differences between spin buttons with and without text input are not perceptible with most screen readers. It is therefore recommended that only spin buttons with a text input option are implemented.

If the spin button is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=spinbutton`.
- If the `spinbutton` role is located at an input field or at an element which contains an input field, it is a spin button with text input. Otherwise, it is a spin button without text input.
- The labeling of the spin button can take place with `aria-label` or `aria-labelledby`. If the ARIA `spinbutton` role is located at an HTML input field, it can also be labeled with `<label for=ID>`.
- The current value must be specified with `aria-valuenow`. If the ARIA `spinbutton` role is located at an HTML input field, its value is used as the current value of the spin button.
- `aria-valuetext` can also be used to specify a value in text form which should be then output by the assistive technology instead of the value in `aria-valuenow`.
- The minimum and maximum values can be specified with `aria-valuemin` and `aria-valuemax`.
- With ARIA spin buttons, specifying an increment is not possible.
- The spin button can be marked as disabled with `aria-disabled` and with `aria-readonly` as read-only.
- The switches used for increasing and/or decreasing the value should not receive keyboard focus separately.
- The presentation of the spin button should be verified in Windows High Contrast mode.
- The visible spin button and the programmatically focused element should have the same position and size.

Practical tip: selection list in Web applications

Screen reader output

During focusing of the selection list:

- JAWS:
 - Without selected list entry: [label] **list field** [instruction on operation with the arrow keys]
 - With selected list entry: [label] **list field** [value] [position] of [amount] [instruction on operation with the arrow keys]

- NVDA:
 - Without selected list entry: [label] **list**
 - With selected list entry: [label] **list** [value] [position] of [amount]
- Windows narrator:
 - Without selected list entry: [label] **requires selection** [amount]
 - With selected list entry: [label] [value] [position] of [amount] **selected** [value] [position] of [amount]

When navigating through the selection list with the arrow keys:

- JAWS: [value] [position] of [amount]
- NVDA: [value] [position] of [amount]
- Windows Narrator: [value] [position] of [amount] **selected**

On reading with the [virtual cursor](#) :

- JAWS:
 - Without selected list entry: [label] **list field**
 - With selected list entry: [label] [value] **list entry** selected [position] of [amount]
- NVDA:
 - Without selected list entry: [label] **list** clickable [first list entry]
 - With selected list entry: [label] **list** clickable [value]
- Windows Narrator: [label] [position] of [amount] [] selected [list entry]

Please note:

- JAWS and NVDA do not output the grouping of an HTML selection list with `<optgroup>`. Windows Narrator only outputs the grouping with `<optgroup>` on reading with the virtual cursor.
- JAWS and NVDA do not output the grouping of an ARIA selection list correctly with `role=group` group. Windows Narrator only outputs the grouping with `role=group` on reading with the virtual cursor.
- When reading with the virtual cursor, JAWS only outputs the selected list entry, NVDA outputs the selected or first list entry, and Windows Narrator outputs all list entries.

HTML

The selection list should be implemented with the HTML elements `<select>` and `<option>` with a value greater than 1 with the `size` attribute and without the `multiple` attribute.

The list entries can be grouped with the `<optgroup>` element. The grouping should be avoided, however, as many screen readers do not output the group label (which is specified with the `label` attribute).

The initially selected list entry can be set with the `selected` attribute. An initial list entry should be selected in each selection list, as keyboard users automatically make a selection when navigating through the selection list

which cannot be undone. The list entry should be initially selected which is either most likely to be selected or which contains a neutral option (e.g. “not applicable”).

The label should be linked to the selection list with the `<label for=ID>` element.

A selection list, a group of list entries and the individual list entries can be marked as disabled (`disabled`), but not read-only (`readonly`).

A selection list can be marked as a required field with `required`.

Further information: [4.10.7 The select element - HTML Standard \(whatwg.org\)](#)

ARIA

If the selection list is not implemented with the HTML element, it is also necessary to take account of the following:

- The selection list is marked with `role=listbox` and contains the list entries that are marked with `role=option`.
- The list entries can be grouped within an element which is marked with `role=group`. The group is labeled with `aria-label` or `aria-labelledby`.
- The selected list entry is marked with `aria-selected=true`, all others with `aria-selected=false`. The selected list entry can also be communicated with `aria-checked` – this is not recommended for selection lists without multiple selection, however.
- Alternatively, the selected list entry is not explicitly marked, but is determined automatically by the focused list entry during the operation. This is not recommended, though, because the assistive technology is not able to reliably determine the selected list entry in the non-focused state.
- The labeling of the selection list can take place with `aria-label` or `aria-labelledby`.
- When navigating through the list entries in the selection list, these must either actually receive the focus, or reference is made to the selected list entry with `aria-activedescendant`. The first variant is to be preferred.
- The selection list can be marked as disabled with `aria-disabled`.
- The selection list can be marked as read-only with `aria-readonly`.
- The selection list can be marked as a required field with `aria-required`.
- A non-standard horizontal orientation of the selection list can be specified with `aria-orientation=horizontal`. Frequently, the orientation is not output by the assistive technology, so that with horizontally oriented list entries, operation with all the arrow keys should be possible.
- The presentation of the selection list should be verified in Windows High Contrast mode.
- The visible selection list and the programmatically focused element should have the same position and size.
- When navigating through the list entries, the focused list entry should be displayed in the visible area.

Multiple selection list

[Online betrachten](#)

Synonyme: List field, multi-line selection list, list box

See also: [Selection list](#) , [drpo-down list](#) , [check box group](#) , [tree structur](#)

Multiple selection lists allow the selection of several options from a list (see DIN EN ISO 9241-161: 8.39).

All the selectable options are displayed in the multiple selection list (with [scrollbrars](#) if necessary). The selected options are highlighted. The options can be grouped. The labeling of the groups cannot be selected. The focused option is not automatically identical to the selected option.

Please select:

- ✓ Option 1
- Option 2
- Option 3
- ✓ Option 4
- Option 5

Figure 44: Multiple selection list (the check mark indicates selected options, the blue background color indicates the currently focused option)

Presentation

The requirements concerning the selection list are described in the “selection list” section. Here, only the additional requirements are described which result from the fact that it is a selection list with multiple selection.

673	Role	The multiple selection list role must be communicated to the Accessibility API (see		

Practical tip: alternatives to the selection list with multiple selection

The possibility for multiple selection is not generally identifiable, as the multiple selection lists do not differ visually from the [selection list](#) . Moreover, multiple selection (in particular the selection of non-neighboring values) with the keyboard and the pointing device is difficult. In addition, the selected elements are often

imperceptible with the screen reader. It is therefore recommended to replace multiple selection lists with other elements, to implement them in a simple form, or to describe their function and operation. Alternatives to multiple selection lists include:

- group of check boxes, or
- two selection list or multiple selection lists side by side, with the first list showing the available values and the second list showing the selected values. Buttons can be used to move values from the first list to the second list or to remove them (see screenshot).

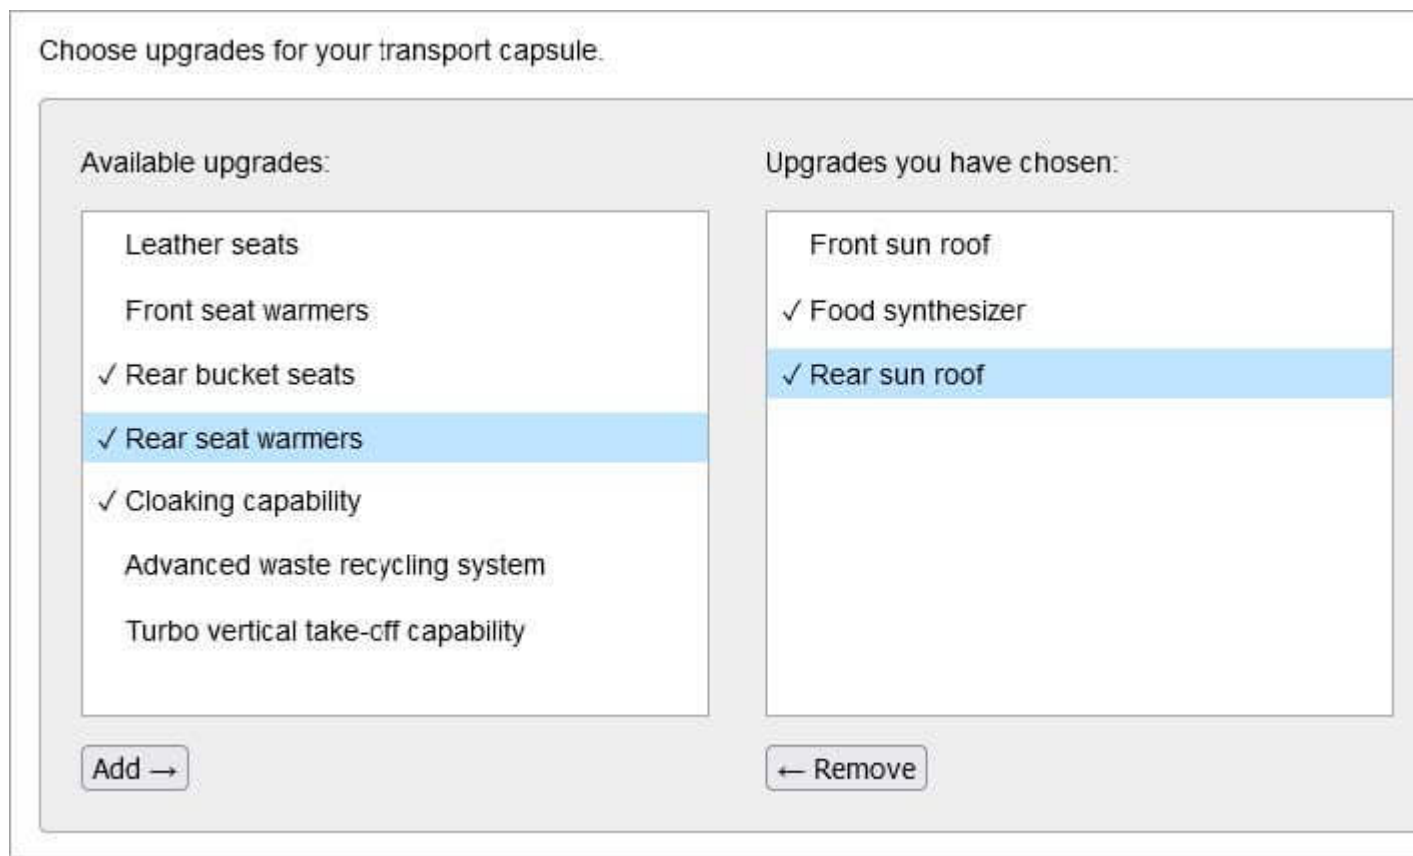

Abbildung: Figure 45: Multiple selection list (WAI-ARIA Authoring Practices 1.2: Listbox > Example Listboxes with Rearrangeable Options)

A simple use of multiple selection lists can be implemented as follows:

- with the pointing device: Click on a value changes the status (selected or unselected)
- with the keyboard: Enabling of a value with the SPACE bar changes the status (selected or unselected).

Practical tip: simplified use of multiple selection

A simple use of multiple selection lists can be implemented as follows:

- with the pointing device: Click on a value changes the status (selected or unselected)
- with the keyboard: Enabling of a value with the SPACE bar changes the status (selected or unselected).

Practical tip: multiple selection list in Web applications

Screen reader output

- JAWS:

- JAWS:
 - Without selected list entry: [label] **extended list field** [instruction on operation with the arrow keys]
 - With selected list entries: [label] **extended list field** [focused list entry] [position and amount] [instruction on operation with the arrow keys]
- NVDA:
 - Without selected list entry: [label] **list**
 - With selected list entries: [label] **list** [focused list entry] [position and amount]
- Windows narrator:
 - Without selected list entry: [label] **selected supports multiple selection** [amount]
 - With selected list entries: [label] [focused list entry] [position and amount] **selected**.

Please note: In the form mode, the selected list entries are imperceptible with the screen reader. The possibility for multiple selection is partly imperceptible. The use of an alternative element is therefore recommended (see [Practical tip: alternatives to the selection list with multiple selection](#)).

HTML

Please note: The use of the keyboard is also difficult for the following reasons:

- Modifier keys, which users may not be familiar with, are required for multiple selection. With old browsers, multiple selection with the keyboard is not possible and/or it is necessary for different modifier keys to be used.
- In the case of multiple selection, the selected list entries are visible, but the currently focused list entry is not.

The use of an alternative element is therefore recommended (see [Practical tip: alternatives to the selection list with multiple selection](#)).

The implementation instructions for the HTML selection list are described in the “selection list” section. Here, only the additional instructions are given, which result from the fact that it is a selection list with multiple selection.

- The multiple selection list should be implemented with the **multiple** attribute.
- The initially selected list entry is marked with the **selected** attribute.

ARIA

The implementation instructions for the ARIA selection list are described in the “selection list” section. Here, only the additional instructions are given, which result from the fact that it is a selection list with multiple selection.

- The possibility for multiple selection is communicated with **aria-multiselectable=true**.

- The selected list entries are marked with `aria-selected=true` or `aria-checked=true`, all others with `aria-selected=false` and/or `aria-checked=false`.
- When navigating through the list entries in the selection list, these must either actually receive the focus, or reference is made to the focused list entry with `aria-activedescendant`. The first variant is to be preferred. In both cases, care must be taken to ensure that the navigation through the multiple selection list does not automatically change the status of the list entries (selected or unselected)

Tree structure

[Online betrachten](#)

Synonyms: Hierarchical list, tree, tree view, structure view

See also: [selection list](#) , [multiple selection list](#) , [hierarchical table](#) , [menu](#)

Tree structures enable the presentation and operation of hierarchically structured lists (see DIN EN ISO 9241-161: 8.17). The nested lists can be shown and hidden. A button with an indicator on the list entries shows whether the subordinate list is shown or hidden. Tree structures can be used for different purposes, for example:

- the selection of one or more list entries within a form (as is the case with a selection list or multiple selection list),
- navigation (as is the case with a [Link](#) list or a menu),
- the showing of data (as is the case with a [list](#)).

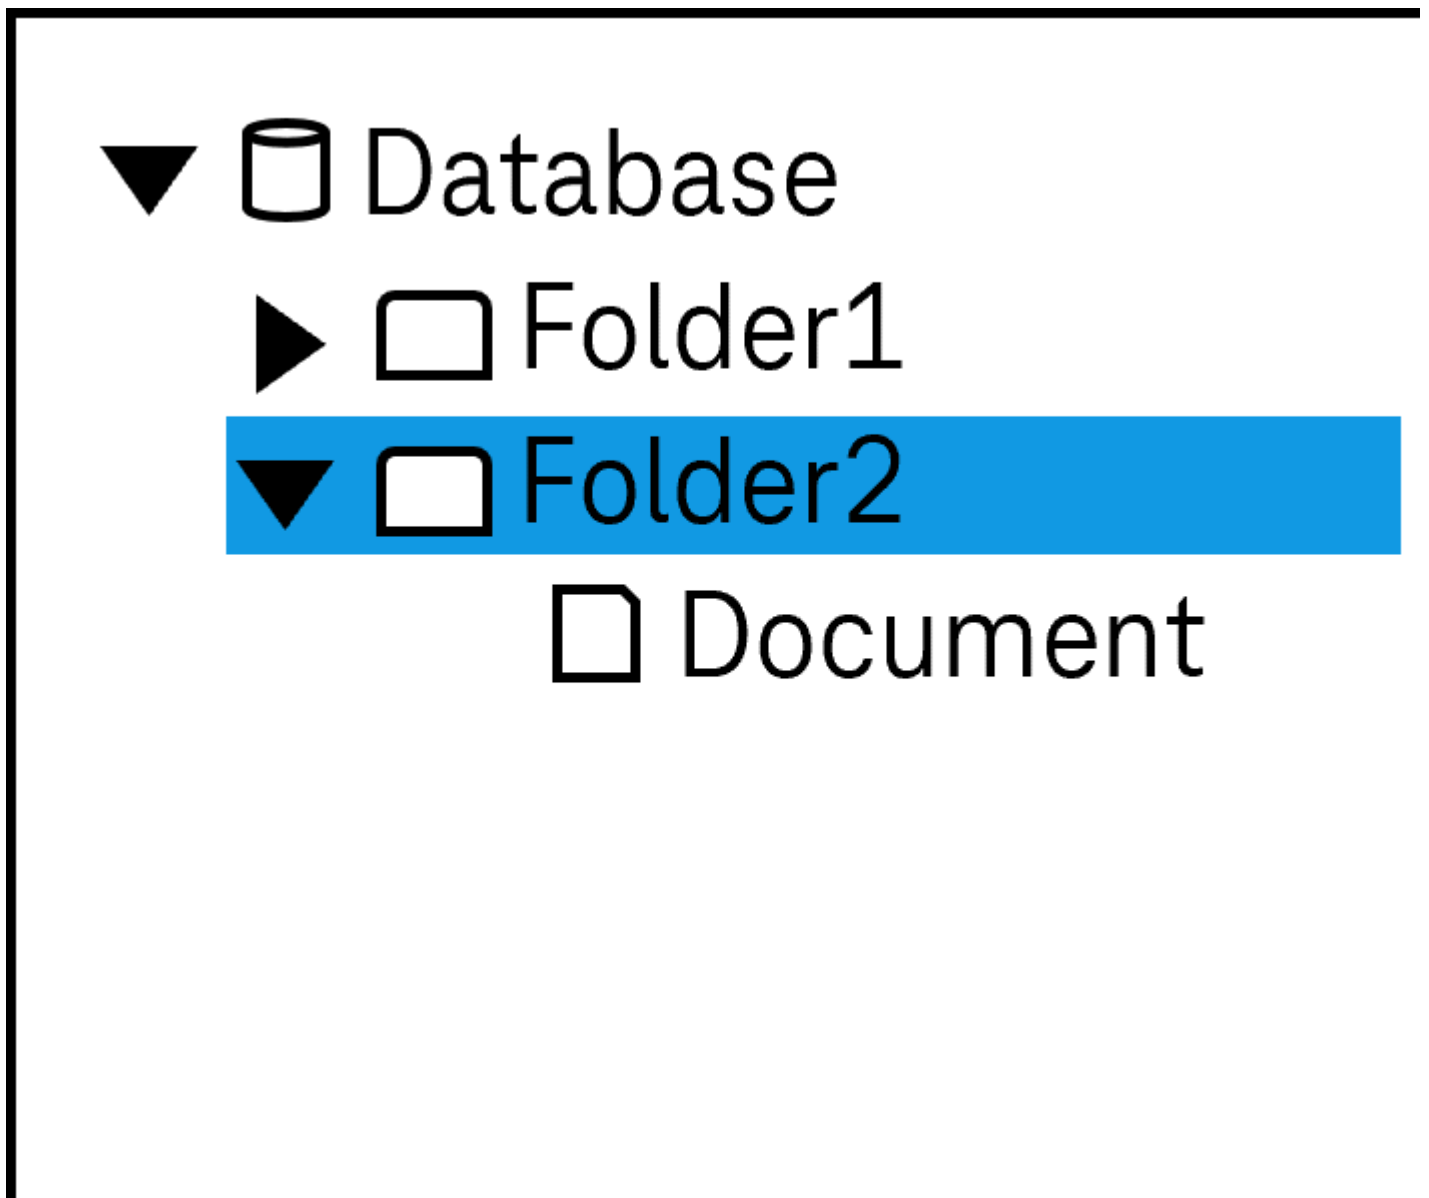

Figure 46: Tree structure

Presentation

[Label](#)). | Must | EN 301 549 9.3.3.2, 11.3.3.2 | | @!679 | Focus visibility | If the tree structure receives the keyboard focus, the focus indicator must be visible (see

[Focus indicator](#)). | Must | EN 301 549: 9.2.4.7, 11.2.4.7 | | @!680 | Focus visibility | When navigating through the list entries, the current list entry must be displayed in the visible area. | Must | EN 301 549: 9.2.4.7, 11.2.4.7 | | @!681 | Option list | It should not be necessary to scroll the tree structure horizontally, i.e. it should be at least as wide as the longest entry. | Must | EN 301 549: 9.2.1.1, 11.2.1.1 | | @!682 | Option list | The list entries should be formulated in such a way that the information that serves the purpose of differentiation is at the beginning. | Should | DIN EN ISO 9241-143: 9.3.4 |

No.	Property	Description	Classification	Reference

Practical tip: tree structures in Web applications

Screen reader output

During focusing of the tree structure:

- JAWS: [label] **structure view** [list entry] [| open | closed] [position] of [amount] [instruction on navigation and operation with the arrow keys]
- NVDA: [label] **tree view** [list entry] [| expanded | reduced] [position] of [amount] level [number]
- Windows Narrator: [label] **structure** [list entry] [position] of [amount] level [number] [| expanded | hidden]

When navigating through the tree structure with the arrow keys:

- JAWS:
 - When changing the level: Level [number] [list entry] [| open | closed] [position] of [amount]
 - Within the same level: [list entry] [| open | closed]
- NVDA:
 - When changing the level: Level [number] [list entry] [| expanded | reduced] [position] of [amount]
 - Within the same level: [list entry] [| expanded | reduced] [position] of [amount] level [number]
- Windows Narrator: [list entry] [position] of [amount] level [number] [| expanded | hidden]

On reading with the [virtual cursor](#) :

- JAWS:
 - without selected element: [label] **structure view**
 - with selected element: [label] **structure element** [list entry] [| expanded | reduced] [position] of [amount]
- NVDA: [label] **tree view** [| expanded | reduced] level [number] [list entry]
- Windows Narrator: [label] **structure** [position] of [amount] level [number] [| expanded | hidden] [list entry]

Please note:

- When reading with the virtual cursor, JAWS only outputs the selected elements (i.e., elements marked with `tabindex=0` or `aria-selected=true`, for example).
- When reading with the virtual cursor, NVDA outputs the first list entry and all the visible nested list entries of the first list entry, but not the selected list entries.
- Windows Narrator outputs all the visible list entries when reading with the virtual cursor.
- Windows Narrator incorrectly outputs “heading level [number]” for each list entry due to the implicit and /or explicit `aria level`.

HTML

There is no element for tree structures in HTML. Instead, the following can be used:

- nested lists (containing the elements ``, ``) with buttons for showing and hiding subordinate list entries which receive focus with the TAB key, or
- Use of the corresponding ARIA roles.

ARIA

With tree structures, the following should be taken into account:

- The tree structure is marked with `role=tree` and contains the list entries that are marked with `role=treeitem`.
- The nested list entries are grouped within an element which is marked with `role=group`. The group itself is located within the superordinate list entry, which is marked with `role=treeitem`.
- The status of the list entries (open or closed) is communicated with `aria-expanded`.
- The current list entry is marked with `aria-selected=true`, all others with `aria-selected=false`.
- List entries can also be marked as enabled and/or not enabled with `aria-checked` as long as the tree structure offers this functionality (e.g. visually, with check boxes at the list entries). If `aria-checked` allows for a multiple selection of list entries, this is communicated with `aria-multiselectable=true`.
- The labeling of the tree structure can take place with `aria-label` or `aria-labelledby`. The labeling of the list entries should take place using text content. The groups are not labeled.
- When navigating through the list entries in the tree structure, these must either actually receive the focus, or reference is made to the selected list entry with `aria-activedescendant`. The first variant is to be preferred.
- The tree structure may not contain any elements apart from the groups and list entries.
- The tree structure can be marked as a required field with `aria-required` and as disabled with `aria-disabled`.
- The presentation of the tree structure should be verified in Windows High Contrast mode. In this respect, the icons that communicate the status of the list entries should be easy to see, for example.

- The visible list entries and the programmatically focused elements should have the same position and size.

Control point

[Online betrachten](#)

Synonyms: Drag point, handle

See also: [Bereichstrenner](#)

A control point is used for the spatial editing of an element such as a graphic, a text block or an application window (see DIN EN ISO 9241-161: 8.16). The control point can, for instance, be used to scale, rotate, distort, or move the element.

A control point often consists of a small circle or square at the corners of the editable element. The editing options can also be shown on the control point. Control points are often only displayed when the corresponding element has focus. With application windows, the control point can also be invisible. A control point can have a [context menu](#) for further functions.

Figure 47: Control point

Presentation

No.	Property	Description	Classification	Reference
702	Role	The control point role must be communicated to the Accessibility API (see		

Note: A control point typically has no visible label. The name of the control point should describe the function (for example, “lower vertical scaling”).

| Must | EN 301 549: 9.2.4.6, 11.2.4.6, 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!707 | Name | If the control point has a description, it must be communicated as an Accessible Description. | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!708 | Operation | It must be possible to access, operate and exit the control point with assistive technology (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.12, 11.5.2.17 | | @!709 | Update | Updates concerning the Accessible Name, value or status of the control point must be communicated to the Accessibility API (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.15 | | @!710 | Desktop: Position | The size and position of the control point must be communicated to the Accessibility API (see

Combined input field

[Online betrachten](#)

Synonyms: Combination field, combo box

See also: [Selection list](#) , [drop-down list](#) , [menu button](#) , [input field with autocomplete function](#)

Combined input fields allow for text input and the selection of options from a list, where the list can be opened and closed (see DIN EN ISO 9241-161: 8.7).

In the closed state, a combined input field consists of an input field and a button (with arrow icon) for opening the list, which is located to the right of the input field. In the opened state, a selection list is displayed underneath (possibly with a [scrollbar](#)). The options of the selection list can be grouped. The labeling of the groups cannot be selected.

Combined input fields can be implemented very differently. The implementation variants include:

- As long as the input field is empty, in the open state, a selection list with all the options is displayed below the input field. If the input field contains text, only options that contain or begin with the text you have already entered appear in the selection list below the input field. If there are no options matching the entered text, no selection list will be displayed.
- The selection list contains certain commonly used values, regardless of the text input.
- The combined input field has two selection lists. The list entries of one list are independent of the text input; in the second list, the matching list entries are only displayed after the text input.
- The text input is used only to filter the options in the selection list. It is not possible to enter text that does not match any of the default options.

Practical tip: combined input field in Web applications

Screen reader output

- JAWS: [label] **combined input field** reduced | expanded [value] [instruction on text input and operation with the arrow keys]
- NVDA: [label] **combo box** reduced | expanded [with autocomplete] editable [value]
- Windows Narrator: [label] [value] **edit combo box** hidden | expanded

HTML

The combined input field should be implemented with the HTML elements `<input type=... list=ID>` and `<datalist id=ID>` and `<option>`.

- The `list` attribute is suitable to be used for the following values in the `type` attribute: `text`, `search`, `url`, `tel`, `email`.
- The `list` attribute may also be used according to the HTML specification with the following values in the `type` attribute. This is not supported by most browsers, however, and sometimes leads to misleading output by the screen readers: `date`, `month`, `week`, `time`, `datetime-local`, `number`, `range`, `color`.

The initial value is communicated through the `value` attribute at the `<input>` element.

The label should be linked to the combined input field with the `<label for=ID>` element.

The combined input field can be marked as a required field (`required`), as disabled (`disabled`) and/or as read-only (`readonly`).

The list entries cannot be marked as disabled or read-only. The list entries cannot be grouped.

Further information: [4.10.8 The datalist element - HTML Standard \(whatwg.org\)](#), [4.10.5.3.9 The list attribute - HTML Standard \(whatwg.org\)](#)

ARIA

Please note: As the ARIA specification regarding `combobox` has changed fundamentally several times in recent years, it cannot be guaranteed that the combined input fields implemented with ARIA will be correctly output by all screen readers. The use of the native combined input field is therefore recommended instead. Alternatively, the ARIA implementation should be thoroughly tested with differing browsers and screen readers.

Please note: The ARIA pattern for combined input fields is often used for input fields with autocomplete function or drop-down lists. These three elements differ in their meaning and operation, however, and should not be mixed up.

If the combined input field is not implemented with the HTML elements, it is also necessary to take account of the following:

- The role is communicated with `role=combobox`. The role must be located at an input field (`<input type=text>`).
- The value of the input field (`value` attribute) is communicated as the value of the combined input field.
- The labeling of the combined input field can take place with `aria-label` or `aria-labelledby`.
- The status of the drop-down list (closed or open = selection list visible) must be communicated with `aria-expanded`.
- Reference is made to the selection list from the element with `role=combobox` using `aria-controls`.
- The autocomplete behavior of the combined input field is communicated with `aria-autocomplete`.
- The selection list is marked with `role=listbox` and its list entries with `role=option`.
- When navigating through the list entries in the selection list, these must either actually receive the focus, or reference is made to the selected list entry with `aria-activedescendant`. The first variant is to be preferred.
- The button with the arrow icon which is able to open the selection list does not receive the keyboard focus (`tabindex=-1`), but should be marked so that it is output by the assistive technology when navigating

with the [virtual cursor](#) . The button should be labeled expressively, refer to the selection list with **aria-controls**, and communicate the status of the selection list with **aria-expanded**.

- The combined input field can be marked as disabled with **aria-disabled**.
- The combined input field can be marked as read-only with **aria-readonly**.
- The combined input field can be marked as a required field with **aria-required**.
- The presentation of the combined input field should be verified in Windows High Contrast mode.
- The visible combined input field and the programmatically focused element should have the same position and size.
- When navigating through the list entries, the focused list entry should be displayed in the visible area.

Drop-down list

[Online betrachten](#)

Synonyms: Dropdown, dropdown list field, combobox

See also: [Selection list](#) , [combined input field](#) , [menu button](#) , [input field with autocomplete function](#)

Drop-down lists allows for the selection of an option from a list, whereby the list can be opened and closed (see DIN EN ISO 9241-161: 8.11).

In the closed status, the current value (the selected option in the list) is displayed and to the right of it, a button (with arrow icon) for opening the list. In the open status, a selection list with all the options is also shown (possibly with a [scrollbar](#)). The current value is highlighted. The options can be grouped. The labeling of the groups cannot be selected.

Practical tip: drop-down list in Web applications

Screen reader output

- JAWS: [label] **drop-down list** [value] [instruction: on operation with the arrow keys]
- NVDA: [label] **combo box** [value] reduced
- Windows Narrator: [label] [value] **combo box** hidden

HTML

The drop-down list should be implemented with the HTML elements `<select>` and `<option>` (without the **multiple** and **size** attributes).

The list entries can be grouped with the `<optgroup>` element. The grouping should be avoided, however, as many screen readers do not output the group label (which is specified with the `label` attribute).

The initially selected list entry can be set with the `selected` attribute.

The label should be linked to the drop-down list with the `<label for=ID>` element. A drop-down list, a group of list entries and the individual list entries can be marked as disabled (`disabled`), but not read-only (`readonly`).

A drop-down list can be marked as a required field with `required`. In this case, however, the first list entry must be empty.

Further information: [4.10.7 The select element - HTML Standard \(whatwg.org\)](https://www.whatwg.org/html/4.10.7)

ARIA

Please note: As the ARIA specification regarding `combobox` has changed fundamentally several times in recent years, it cannot be guaranteed that the ARIA drop-down list will be correctly output by all screen readers. The use of the HTML drop-down list is therefore recommended instead. Alternatively, the ARIA implementation should be thoroughly tested with differing browsers and screen readers.

Please note: Depending on the operating system, an HTML drop-down list is communicated to the Accessibility API differently. Under MacOS, a drop-down list is a menu button which opens a menu. If an ARIA drop-down list is used, no cross-platform solution is possible, as it would be necessary to use either the `combobox` role for Windows or the `button` role with `aria-haspopup=menu` for MacOS. The use of HTML drop-down lists is therefore recommended.

If the drop-down list is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=combobox`. The role may not be located at an input field. Instead of this, a `<div>` element should be used.
- The text content of the element with `role=combobox` is communicated as the value of the drop-down list.
- The button with the arrow icon which is able to open the selection list is marked so that it does not receive the keyboard focus and is not output by the assistive technology (e.g. with `aria-hidden=true`).
- The labeling of the drop-down list can take place with `aria-label` or `aria-labelledby`.
- The status of the drop-down list (closed or open = selection list visible) must be communicated with `aria-expanded`.
- Reference is made to the selection list from the element with `role=combobox` using `aria-controls`.
- The selection list is marked with `role=listbox` and its list entries with `role=option`.
- When navigating through the list entries in the selection list, these must either actually receive the focus, or reference is made to the selected list entry with `aria-activedescendant`. The first variant is to be preferred. -The drop-down list can be marked as disabled with `aria-disabled`.
- The drop-down list can be marked as read-only with `aria-readonly`.
- The drop-down list can be marked as a required field with `aria-required`.

- The presentation of the drop-down list should be verified in Windows High Contrast mode.
- The visible drop-down list and the programmatically focused element should have the same position and size.
- When navigating through the list entries, the focused list entry should be displayed in the visible area.

Slider

[Online betrachten](#)

Synonyms: Analog form element, range slider, range control

See also: [Spin button](#) , [radio buttons](#) , [drop-down list](#) , [scrollbar](#) , [separator](#) , [progress bar](#)

A slider is used to select a value from a continuous range of values (see DIN EN ISO 9241-161: 8.2). Sliders are mainly used for numerical values.

A slider consists of a bar that represents the entire range of values and a drag point which displays the selected value and through which the value is changed. Sliders can also feature an unlabeled or labeled scale of values on the bar. A slider can be aligned vertically or horizontally.

Amount

Practical tip: sliders in Web applications

Screen reader output

- JAWS: [label] **up down slider** | **left right slider** [value] [instruction on operation with the arrow keys]
- NVDA: [label] **slider** [value]
- Windows Narrator: [label] **slider** with [value] current value [value] lowest value [minimum value] highest value [maximum value]

HTML

The slider should be implemented with the HTML element `<input type=range>`. The initial value can be set with the `value` attribute.

The minimum and maximum values and increment are set with the `min`, `max` and `step` attributes. It should be noted that these values are imperceptible with many forms of assistive technology.

The label should be linked to the slider with the `<label for=ID>` element.

A slider can be marked as disabled (`disabled`), but not read-only (`readonly`) or as a required field (`required`).

It is not possible to set the orientation of the slider. Most browsers display the slider horizontally.

Further information: [4.10.5.1.13 Range state \(type=range\) - HTML Standard \(whatwg.org\)](#)

ARIA

Please note: On mobile devices, an ARIA slider may not be operated with assistive technology, because no gesture commands for the operation of non-native sliders have been implemented.

If the slider is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=slider`.
- The current value must be specified with `aria-valuenow`.
- The minimum and maximum values can be specified with `aria-valuemin` and `aria-valuemax`.
- The labeling can take place with `aria-label` or `aria-labelledby`.
- The presentation of the slider should be verified in Windows High Contrast mode.
- The visible slider and the programmatically focused element should have the same position and size.

The ARIA slider differs from the HTML slider in the following ways:

- An increment cannot be specified.
- The orientation can be specified with `aria-orientation`. Frequently, the orientation is not output by the assistive technology, so that the operation with all the arrow keys should be possible.
- `aria-valuetext` can also be used to specify a value in text form which should be then output by the assistive technology instead of the value in `aria-valuenow`.
- Sliders with multiple drag points can be implemented for the selection of a range of values, for example.
- The slider can be marked as read-only with `aria-readonly`.

Scrollbars

[Online betrachten](#)

Synonyms: Scrollbar

See also: [Slider](#) , [pagination](#) , [carousel](#) , [control point](#)

A scrollbar is for scrolling through the entire page, part of a page or parts of an element (such as list entries in a drop-down list) in the visible area. The scrollbar also serves the visualization of the current position and the overall size of the page, parts of the page or elements (see DIN EN ISO 9241-161: 8.35).

A scrollbar consists of a moving bar and the scroll box. The moving bar represents the total length or width of the scrollable area. The scroll box shows the location and size of the visible section and also allows the visible section to be moved.

At the start and end of the moving bar there is generally a button with an arrow icon for incremental scrolling.

Vertical scrollbars are located on the right-hand border of the scrollable area. Horizontal scrollbars are located on the lower border of the scrollable area.

Practical tip: radio buttons in Web applications

Screen reader output

- JAWS: [group label] [label] **selection button** enabled | not enabled [position and amount] [instruction on operation with the arrow keys]
- NVDA: [group label] **grouping** [label] **selection button** enabled | not enabled [position and amount]
- Windows Narrator: [label] **option field** selected | not selected [position and amount]

HTML

The radio button group should be marked with the HTML element `<fieldset>` and labeled with the `<legend>` element.

The radio buttons should be implemented with the HTML element `<input type=radio>`. Radio buttons that belong to the same group must have the same value in the `name` attribute and may not be located in different `<form>` elements.

The initially selected status is set with the `checked` attribute. An initial radio button should be selected in each radio button group, as keyboard users automatically make a selection when navigating through the radio buttons which cannot be undone. The radio button should be initially selected which is either most likely to be selected or which contains a neutral option (e.g. “not applicable”).

The label should be linked to the respective radio button using the `<label for=ID>` element in order to expand the click area of the radio button by its label.

A radio button and the radio button group can be marked as disabled (`disabled`), but not as read-only (`readonly`).

If a radio button is marked as a required field with `required`, this applies to the entire radio button group, i.e. if any radio button was selected, this is sufficient for submitting the form. To ensure that the required field label is perceptible with the assistive technology on all radio buttons, using the `required` attribute on all radio buttons, or alternatively, adding a required text field reference (e.g. an asterisk) in the group label (`<legend>`) is recommended. If a radio button is initially preselected with the `checked` attribute, no required field label is required.

Error messages should not be associated with each individual radio button, but with the group.

Further information: [4.10.5.1.16 Radio Button state \(type=radio\) - HTML Standard \(whatwg.org\)](#)

ARIA

If the radio button group is not implemented with the HTML element, it is also necessary to take account of the following:

- The radio buttons are located in an element which is marked with `role=radiogroup`.
- The radio button group can be labeled with `aria-labelledby` or `aria-label`.
- The role of the radio buttons is communicated with `role=radio`.
- The status is communicated with `aria-checked=true|false` and must be updated during operation.
- The labeling of the radio buttons can take place using text content or `aria-labelledby`.
- The radio button group can be marked as read-only with `aria-readonly`. The radio buttons cannot be marked as read-only.
- In contrast to HTML, `aria-required` is not used to mark the radio buttons as a required input, but the radio button group (`role=radiogroup`).
- The presentation of the radio buttons should be verified in Windows High Contrast mode.
- The visible radio buttons and the programmatically focused elements should have the same position and size.

Further information: [radio role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#), [radiogroup role - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\) \(External Link\)](#), [Radio Group Pattern | APG | WAI | W3C](#), [Checkbox Pattern | APG | WAI | W3C](#)

Check box

[Online betrachten](#)

Synonyms: Control box, control field, selection box

See also: [Toggle switch](#) , [switch](#) , [radio buttons](#) , [selection list with multiple selection](#)

A check box serves the selection of the options “selected” or “not selected” (see DIN EN ISO 9241-161: 8.4). A check box can also relay the status of a subordinate check box group (“all selected”, “none selected” or “some selected”).

A check box consists of a square frame and an indicator (check mark) which indicates whether the check box has been selected, has not been selected, or whether some of the subordinate group have been selected.

Practical tip: check box in Web applications

Screen reader output

- JAWS: [label] **check box** enabled | not enabled | partially enabled [instruction on operation with the space bar]
- NVDA: [label] **check box** enabled | not enabled | partially enabled
- Windows Narrator: [label] **check box** enabled | not enabled | indeterminate

HTML

The check box should be implemented with the HTML element `<input type=checkbox>`.

The initially selected status is set with the `checked` attribute. The “some selected” state can only be set using JavaScript with the `indeterminate=true` characteristic.

The labeling of the check box should be linked to the check box using the `<label for=ID>` element in order to expand the click area of the check box by its label.

A check box can be marked as disabled (`disabled`), but not as read-only (`readonly`).

A check box can be marked as a required field with `required`. This is only useful in cases where the check box has to be submitted in the “selected” (`checked`) status. However, if at least one check box in a group of check boxes must be selected, the check box should not be marked with `required`, but the required field label should be implemented in the group. As the group cannot be marked with `required`, the required field label should be in text form (e.g. an asterisk within the group label).

Check boxes that belong together should be positioned within a labeled [Form field group](#) . The `<fieldset>` element is used for the group and the `<legend>` element is used for the group label.

Error messages that do not relate to a single check box but to the check box group should not be linked to each individual check box but to the group.

Further information: [4.10.5.1.15 Checkbox state \(type=checkbox\) - HTML Standard \(whatwg.org\)](#)

ARIA

If the check box is not implemented with the HTML element, it is also necessary to take account of the following:

- The role is communicated with `role=checkbox`.
- The status is communicated with `aria-checked=true|false|mixed` and must be updated during the operation.
- The labeling can take place by text content or `aria-labelledby`.
- The check box can be marked as read-only with `aria-readonly`.

- The presentation of the check box should be verified in Windows High Contrast mode.
- The visible check box and the programmatically focused element should have the same position and size.

Composite form fields

[Online betrachten](#)

Composite form fields consist of two or more form fields that have a visual label.

The requirements for the individual form fields are described for the respective form field type. Here, only the additional requirements are described which result from the fact that a label refers to several fields.

Date: .

Address

First name & surname:

Street & house number

Zip code & location:

Figure 55: Composite input fields

Presentation

No.	Property	Description	Classification	Reference
824	Label	Each form field should have a tooltip that contains the specific label. Note: In the address form, this would be „zip code“ or „location“. In the case of form fields for the time period, this is, for example, „start“ and „end“.	Should	DIN EN ISO 9241-143: 9.6.11

Programming/interfaces

[Practical tip: composite form fields](#)). | Must | EN 301 549: 9.2.5.3, 11.2.5.3 |

No.	Property	Description	Classification	Reference
825	Name	Each form field must have a concise and expressive Accessible Name. Note: In the address form, this would be „zip code“ or „location“. In the case of form fields for the time period, this is, for example, „period: start“ and „period: end“ .	Must	EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5, 11.5.2.8
826	Name	The visible label must match with or be contained in the Accessible Name (see		

Practical tip: composite form fields

With composite form fields, the following problems may arise:

- The spacing between the label and the form field is often greater, which makes the purpose of the form fields more difficult to identify, when using a screen magnifier or for cognitively disabled people, for example.
- Each field requires an expressive Accessible Name which is communicated to the Accessibility API, even if the field does not visually have an explicit label.
- The visible label must match with or be contained in the Accessible Name, even if the visible label refers to several fields.
- In applications that support the [virtual cursor](#) , the reading sequence with the screen reader may not be correct, for example, because the labels of the fields are output first, followed by the form fields (without the label being output again).

For these reasons, we recommend that the use of composite form fields is avoided and each field is assigned a label visually and programmatically.

Otherwise, and at the least, the following information should be taken into account:

- If the visual label contains only one overarching label, (e.g. „date“ for three date fields in which the day, month and year are entered), these should be included in the Accessible Name together with a clear label (e.g. „date day“, „date month“, „date year“). Alternatively, a field can be used for entering the full date, for example.
- If the visual label contains the label of each field (for example, „zip code“ and „location“), the Accessible Name should match with the individual labels (for example, „zip code“ and „location“).
- Complex forms should be generally redesigned in order to meet accessibility requirements. The following screenshot, for example, contains two radio buttons with the „on“ label in an unlabeled group. From the visual context, it can be seen that the first radio button refers to a repetition of a recurring event on an explicitly defined date, while the second refers to the repetition on an implicitly defined day of the week. The group labeling of the radio buttons could be „repeat on one“, and the radio buttons themselves could be labeled visually and programmatically with „date“ and „day of the week“, whereby the currently selected date or the currently selected day of the week can be communicated as the Accessible Description. The form fields that are located behind the two radio buttons and which allow for the selection of the date or day of the week should be explicitly labeled.

Figure 56: Complex form field (Outlook: New Items > Appointment > Make Recurring)

Accordion

[Online betrachten](#)

See also : [Button](#) , [tabs](#) , [carousel](#)

An accordion combines several areas which are arranged one beneath the other and which can be shown and hidden using buttons. In this respect, the labeling of the areas is visible at all times (see DIN EN ISO 9241-161: 8.1). The label usually has a visual indicator which refers to the status of the area (shown or hidden). For an accordion, different implementation variants are possible with respect to the minimum or maximum number of open areas, e.g.

- Initially, all the areas are closed and only one area can be opened at a time. If an area is opened, the previously opened area is automatically closed.
- At least one area is open at all times, and all areas can be opened.

Area 1

Area 2

Practical tip: accordion in Web applications

Screen reader output for the accordion buttons for showing and hiding the areas

- JAWS: [Label] **Button** [reduced | expanded] [note on operation with the Enter key]
- NVDA: [Label] **button** [reduced | expanded]
- Windows narrator: [Label] **button** [hidden | expanded]

Note: When using the `<details>`-element without a label, the beginning and end of the page area are not perceptible with assistive technology. If the `<details>`-element is explicitly labeled (by `aria-label` or `aria-labelledby`) the area is output as „group“ (JAWS) or „grouping“ (NVDA). Die Windows Narrator does not output labeled groups either.

HTML

There is no element for accordions in HTML. Instead, several areas can be used which are shown and hidden using buttons. The areas are marked with `<details>` and the buttons with `<summary>`. The `<summary>` element is the first child element within `<details>`. The labels of the buttons are derived from the text content in the `<summary>` element. The initial state of the area (opened or closed) is set with the `open` attribute.

To make the coherence of the areas and buttons perceptible with assistive technology, they can be nested in a labeled group.

According to the HTML specification, the `<summary>` element may contain links, headings, input fields and many other elements – it is important to remember, however, that all the elements which are located within `<summary>` are imperceptible and cannot be operated with the screen reader, as the `<summary>` element is communicated to the Accessibility API as a button. Therefore, the `<summary>` element should only contain a concise and expressive label in text form.

Further information: [4.11.1 The details element - HTML Standard \(whatwg.org\) \(External Link\)](#), [4.11.2 The summary element - HTML Standard \(whatwg.org\) \(External Link\)](#)

ARIA

There is no role for accordions in ARIA. Instead, several areas can be used which are shown and hidden using [Button](#). In this respect, the following should be taken into account:

- The buttons that have the purpose of showing and hiding areas should be marked with the `aria-expanded` attribute. `aria-controls` can be used to make reference to the ID of the area that is shown or hidden.
- The labeling of the buttons should take place using text content or `aria-labelledby`.

- To make the coherence of the areas and buttons perceptible with assistive technology, they can be nested in a labeled [group](#) .
- The presentation of the accordion should be verified in Windows High Contrast mode. The areas should therefore have a border.
- The visible button and the programmatically focused element should have the same position and size.

Alternatively, a [tab group](#) can be used instead of an accordion.

Further information: [aria-expanded state - Accessible Rich Internet Applications \(WAI-ARIA\) 1.2 \(w3.org\)](#)

, [Accordion Pattern \(Sections With Show/Hide Functionality\) | APG | WAI | W3C](#)

Date picker

[Online betrachten](#)

Synonyms: Calendar date picker, calendar, calendar element, calendar control, time selector, time picker, clock, date and time selector, date-time picker

See also: [Combined input field](#) , [color picker](#)

Note: All the following statements apply equally to the time picker or to control elements for the selection of weeks, months or years.

A date picker is used for the supported entry of a date (see DIN EN ISO 9241-161: 8.9 and 8.46).

Date pickers can be implemented in different ways, e.g. as

- [input field](#) for a date combined with a [button](#) , with which it is possible to open a dialog for the selection of a date,
- read-only input field for a date combined with a button with which it is possible to open a dialog for the selection of a date,
- [combined input field](#) for a date with which it is possible to open a dialog for the selection of a date,
- [table](#) for selecting a date within a specific time period and buttons for changing the time period,
- separate input fields for entering the day, month and year, combined with a button with which it is possible to open a dialog for the selection of a date,
- separate [spin buttons](#) for entering and selecting the day, month and year,
- separate [selection lists](#) for selecting the day, month and year,
- separate [drop-down lists](#) for selecting the day, month and year.

The dialog for selecting a date can contain the following elements:

- Tables, buttons, [radio buttons](#) , spin buttons, selection lists or drop-down lists for selecting a date within a specific period of time (e.g. days within a month, months within a year, years within a decade),
- Buttons for selecting another period,
- visual highlighting of the days and periods (e.g. „today“, „chosen day“, „holiday day“, „public holiday“, „weekend“, „day with free appointments“). The requirements for the individual control elements within the date picker are described for the respective control element. Only the additional requirements for the whole of the element are described here.

Activation of the control elements in the color picker	left click	Required

Programming/interfaces

[Accessibility API](#)). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!869 | Desktop: Element hierarchy | The parent / child relationships of the elements within the color picker must be communicated to the Accessibility API. | Must| EN 301 549: 11.5.2.9 | | @!870 | Status, value | The value and status of the color picker and its control elements must be communicated to the Accessibility API (see

[Element status](#)).

Note 2: Value refers, for example, to the selected color or the value of a color channel. Color names are to be preferred over color values.

No.	Property	Description	Classification	Reference
868	Role	The role of the color picker and its control elements must be communicated to the Accessibility API (see		

Note 1: Status refers, for example, to the „open“ or „closed“ status with respect to the dialog, and to the „selected“ status with respect to the selected color within one of the selection elements.

| Must | EN 301 549: 11.4.1.2, 11.5.2.5 | | @!871 | Name | The color picker and its control elements must have a concise and expressive Accessible Name. | Must| EN 301 549: 9.2.4.6, 11.2.4.6, 9.4.1.2, 11.4.1.2, 11.5.2.5, 11.5.2.8 | | @!872 | Name | If the color picker or its control elements have a description, it must be communicated as an Accessible Description. | Must| EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!873 |

No.	Property	Description	Classification	Reference
Operation It must be possible to access, operate and exit the color picker and its control elements with assistive technology (see Accessibility API). Must EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.12, 11.5.2.17 @!874 Update Updates concerning the Accessible Name or status of the color picker and its control elements must be communicated to the Accessibility API (see Accessibility API). Must EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.15 @!875 Desktop: Position The size and position of the color picker and its control elements must be communicated to the Accessibility API (see Accessibility API). Must EN 301 549: 11.5.2.5, 11.5.2.13				

Practical tip: color picker in Web applications

HTML

The color picker can be implemented with the HTML element .

The initial value is communicated through the value attribute. Only the hexadecimal color values starting with a diamond and followed by 6 characters are permitted as values.

The label of the color picker should be linked to the color picker with the element.

The color picker can be marked as disabled, but not as a required field (required) or as read-only (readonly).

Please note: Depending on the browser and screen reader used, the HTML color picker is either not perceptible at all (e.g. JAWS with Chrome and Edge) or only partially perceptible and operable (e.g. NVDA with Chrome, Edge and Firefox). Using the HTML color picker is not recommended, unless the application is only intended to work with a browser and specific assistive technology, and accessibility can be guaranteed in this environment.

Otherwise, depending on the requirement, for instance, a [button](#) , which opens a [modal dialog](#) for the color selection, one or several [input fields](#) , a [drop-down list](#) , [slider](#) or a combination of these elements can be used.

Further information: [4.10.5.1.14 Color state \(type=color\) - HTML Standard \(whatwg.org\)](#)

ARIA

There is no role for color pickers in ARIA. Instead, depending on the requirement, for instance, a button which opens a modal dialog for the color selection, one or several input fields, a drop-down list, slider or a combination of these elements can be used.

Carousel

[Online betrachten](#)

Synonyms: Slide show, diashow, image rotator, cover flow, element flow, slider

See also: [Accordion](#) , [Tabs](#)

A carousel is used for the grouping of blocks of content that can be scrolled through (see DIN EN ISO 9241-161: 8.3).

Several implementation variants are possible, including:

- Only one content block is visible at a time, several content blocks are visible, or all content blocks are visible.
- The visible content blocks are completely visible, conceal each other or are truncated at the edge of the screen.
- The content blocks are arranged vertically or horizontally side by side, in a circle, or one above the other.
- All visible content blocks are displayed in the same way or a central content block is highlighted, while the content blocks are displayed adjacently in smaller form or grayed out.
- It is possible to scroll through the content blocks automatically or this can be done by the user. - The scrolling through the content blocks takes place using a [scrollbar](#) , [button](#) for scrolling back and forth, or with a [pagination](#) .
- The content blocks may contain graphical elements, text, and control elements.

Examples:

Figure: Carousel

Presentation

[animations](#)).

[focus indicator](#)). | Must | EN 301 549: 9.2.4.7, 11.2.4.7 |

No.	Property	Description	Classification	Reference
876	Contrast	If the control elements of the carousel are labeled with text, they must have a contrast ratio of at least 4.5:1.	Must	EN 301 549: 9.1.4.3, 11.1.4.3
877	Contrast	If the control elements of the carousel are labeled with graphics, they must have a contrast ratio of at least 3:1.	Must	EN 301 549: 9.1.4.11, 11.1.4.11
878	Contrast	If, in terms of the pagination, the current page only differs from the rest of the pages due to its color, the colors must have a contrast ratio of at least 3:1.	Must	EN 301 549: 9.1.4.1, 11.1.4.1
879	Animation	If the content blocks in the carousel are scrolled through automatically, a mechanism must be implemented to stop the automatic scrolling and it must then be possible to scroll through the content blocks manually.	Must	EN 301 549: 9.2.2.1, 11.2.2.1, 9.2.2.2, 11.2.2.2
880	Animation	If moving animations are displayed during the operation of the carousel, a mechanism should be available to disable them(see)		

Note: This applies to scrolling through the content blocks, for example..

| Should | WCAG 2.1.: 2.3.3 (AAA) | | @!881 | Focus visibility
 | If an element in the carousel receives the keyboard focus, the focus indicator must be visible(see

Operation

[change of context](#) may occur. | Must | EN 301 549: 9.3.2.1, 11.3.2.1 | | @!884 | Updates | When operating the carousel, no loss of focus may occur.

[navigation sequence](#)) | Should | DIN EN ISO 9241-171: 9.3.17 | | @!887 | Click area | The click area of the control elements of the carousel should be at least 24 x 24 px (see

[use of the pointing device](#)). | Should | WCAG 2.2 |

No.	Property	Description	Classification	Reference
882	Use of the keyboard	It must be possible to access, operate and exit the carousel and the elements that it contains with the keyboard (see Use of the keyboard table, below).	Must	EN 301 549: 9.2.1.1, 11.2.1.1, 9.2.1.2, 11.2.1.2
883	Use of the keyboard	The hidden content blocks and their contents must not receive keyboard focus.	Must	EN 301 549: 9.1.3.1, 11.1.3.1
884	Updates	During the focusing of the control elements of the carousel, no		

Note: The focus must remain on the respective control element or be placed at the beginning of the shown area.

| Must | EN 301 549: 9.2.4.3, 11.2.4.3 | | @!885 | Focus order | The focus order in the carousel should be appropriate to the work task. | Should | DIN EN ISO 9241-171: 9.3.18 | | @!886 | Focus order | If the carousel contains several control elements that receive the focus with TAB, it should be possible to skip the carousel with the keyboard (see

Use of the keyboard: carousel

Action	Key	Classification
Focusing of the first element in the carousel	TAB	Required
Exiting the carousel	TAB Note: There can be several control elements within the carousel that have been previously focused with TAB.	Required
Navigating within the carousel	TAB or LEFT/RIGHT/UP/DOWN ARROW (depending on the used control element)	Required
Quick navigation between the content blocks	POS1, END, PAGE UP/DOWN	Recommended
Activating of the control elements in the carousel	ENTER or SPACE (depending on the used control element)	Required

Use of the pointing device: carousel

Action	Key	Classification
Enabling of the control elements in the carousel	left click	Required

Programming/interfaces

[Accessibility API](#)).

[Element status](#)).

[Focus indicator](#)). | Must | EN 301 549: 11.5.2.5, 11.2.5.13 |

No.	Property	Description	Classification	Reference
888	Role	The role of the control elements in the carousel must be communicated to the Accessibility API (see		

Note: If the carousel role is not known in the programming language used, the entire carousel should be located in a labeled group. The label or description of the group should contain a note about the element type of the carousel.

| Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!889 |
 Status | The status of the content blocks and control elements in the carousel must be communicated to the Accessibility API (see

Note: This also applies to the “current content block” status in the carousel or the pagination.

| Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!890 |
 Name | The control elements in the carousel must have a concise and expressive Accessible Name. | Must | EN 301 549: 9.2.4.6, 11.2.4.6, 9.4.1.2, 11.4.1.2, 11.5.2.5, 11.5.2.8 | | @!891 |
 Name | If the control elements in the carousel have a description, it must be communicated as an Accessible Description. | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.5 | | @!891 |
 Operation | It must be possible to access, operate and exit the carousel and its control elements with assistive technology (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.12, 11.5.2.17 | | @!892 |
 Update | Updates concerning the Accessible Name or status of the content blocks and the control elements in the carousel must be communicated to the Accessibility API (see Accessibility API). | Must | EN 301 549: 9.4.1.2, 11.4.1.2, 11.5.2.15 | | @!893 |
 Desktop: Position | The size and position of the content blocks and the control elements in the carousel must be communicated to the Accessibility API (see

Glossary

[Online betrachten](#)

Accessibility

The extent to which products, systems, services, environments and facilities can be used by people from a population with the widest scope of use-related needs, characteristics and skills to be able to achieve identified objectives in identified use contexts (EN 301 549 v3.2.1:2021)

Accessible methods of access include construction and other facilities, methods of transport, technical objects, information processing systems, acoustic and visual information sources and communication devices and other designed areas of life, if they can be found, accessed and used by persons with disabilities in the usual way, without any particular difficulties and in general without assistance from others. In this respect, the use of necessary auxiliaries due to disability is permitted (Section 4 of the BGG).

Accessible Description

Programmatically interpretable characteristic of a UI element that has the purpose of the more detailed description of the UI element for assistive technology

Accessible Name

Name; Programmatically interpretable characteristic of a UI element that has the purpose of the labeling of the UI element for assistive technology

Area navigation

The ability to move from one UI element group to another with the use of the keyboard

Assistive Technology

AT; Product, system, hardware or software which is used to enhance, maintain or improve the functional skills of people (EN 301 549 v3.2.1:2021)

Examples: Screen magnifier, screen reader, text-to-speech software, speech recognition software, alternative keyboards and pointing devices ([assistive technology - Web Content Accessibility Guidelines \(WCAG\) 2.2 \(w3.org\)](#) (External Link)) (w3.org))

Authoring Tool

Software which can be used to create or edit content (EN 301 549 v3.2.1: 2021)

Captcha

„Completely Automated Public Turing test to tell Computers and Humans Apart“ Program that protects websites from bots by generating and evaluating tests that people are able to pass but current computer programs are not ([Official CAPTCHA page](#) (External Link))

Click area

The area of the user interface which is activated by a pointer device (e.g. a mouse) (DIN EN ISO 9241-161:2016)

Closed functionality

Functionality which is restricted by specific features that prevent the connection, installation or use of assistive technology (EN 301 549 v3.2.1:2021)

Color scheme

Series of color assignments for the presentation of UI elements (DIN EN ISO 9241-171)

Context-sensitive Help

Help text that contains information about the function which is currently being run

Note: Unique labels can be used as context-sensitive help.

Examples:

- Link to the Help option
- Digital input assistant
- Spell check
- Word suggestions during text input
- Suggestion of alternative words in the case of incorrect entries
- Tooltips [context-sensitive help - Web Content Accessibility Guidelines \(WCAG\) 2.1 \(w3.org\) \(External Link\)](#)

Continuous text

Also scrolling text or text block; continuous text of an article without a heading, table or equivalent; Text with more than one sentence (WCAG 2.1, Understanding SC 1.4.8)

Contrast ratio

Evaluation of the difference between two immediately adjacent or sequential impressions (luminance contrast, brightness contrast, color contrast, etc.)

Here: Measurement value for the presentation of the maximum relative brightness differences between two colors

Control element

Control, operating element;

UI element with which users are able to interact, such as the keyboard or a pointing device

Examples: Links, buttons, form fields

Custom element

UI element which, in contrast to defined UI elements of the programming language (standard elements), can be created by development teams with full functionality

Description

The detailed labeling for a UI element (input field, display field, a table, a control element or an object)

ENTER key

This refers to both the RETURN and ENTER keys on the numeric keypad

Explicit identifier

Code or abbreviation for a menu item or the label of a control element (usually on the left) which is highlighted next to the name and entered when selected (DIN EN ISO 9241-171:2008)

Flash

A series of two opposing changes in relative luminance. If the changes are big enough and occur at the correct frequency, they pose the risk of triggering seizures in some people. ([general flash and red flash thresholds - Web Content Accessibility Guidelines \(WCAG\) 2.1 \(w3.org\) \(External Link\)](#))

Focus indicator

Position cursor;

Display that shows which UI element has the keyboard focus (DIN EN ISO 9241-171:2008) For example:
Keyboard focus indicator: visual display of where the user interaction with the keyboard (or keyboard emulator) will take place (DIN EN ISO 9241-171:2008)

Form

structured presentation of fields and other UI elements that users read, fill out, for which they select or modify entries (DIN EN ISO 9241-161:2016)

Form element

UI element which is used for entering or selecting values in form dialogs (also buttons)

Hard line break

fixed end-of-line marking which is interpreted as a paragraph (pilcrow, symbol: ¶) ([automatic line break - Wikipedia](#))

Hover area

The area of the user interface which responds to an overlying pointer (DIN EN ISO 9241-161:2016)

Hybrid application

Desktop application that uses Web technologies for the presentation of the user interface

Image of text

Text which is rendered in a non-text form (e.g., an image) to achieve a particular visual effect ([image of text - Web Content Accessibility Guidelines \(WCAG\) 2.1 \(w3.org\) \(External Link\)](#))

Implicit identifier

The part of an option name or the label of a control element which is used for a keyboard selection (DIN EN ISO 9241-171:2008)

For example „Print“

Keyboard

here: Keyboard interface;

Interface which is used by the software for the receiving of keystrokes ([keyboard interface - Web Content Accessibility Guidelines \(WCAG\) 2.1 \(w3.org\) \(External Link\)](#))

Keyboard focus

current assignment of the input made on a keyboard or keyboard equivalent to a UI element (DIN EN ISO 9241-171:2008)

Keyboard navigation

The ability to move from one UI element to another within an interactive system with the use of the

Keyboard shortcut

Key shortcut, key combination, keyboard combination, keyboard command, keyboard equivalents, key sequence, access key, hot key, shortcut

Keys and key combinations which provide access to functions that are usually activated by means of a pointing device, voice input, or through other input or control mechanisms

Label

A short designation or heading for a UI element (for example, an input field or display field, a table, a control element or an object) (see also DIN EN ISO 9241-171: 2008)

Navigation

The ability to move from one UI element to another within a single user interface and to move within an interactive system (DIN EN ISO 9241-161:2016)

Non-text content

Content which is not a sequence of letters determinable by software, or in the case of which the sequence does not express anything in human language (EN 301 549 v3.2.1:2021)

Examples:

- Captcha

- Sound
- Graphic
- Vibration
- ASCII-Art

Open functionality

Functionality which supports the access through assistive technology (EN 301 549 v3.2.1:2021)

Platform software

A collection of software components which is run on an underlying software or hardware layer, and which provides a set of software services to other software components through which these applications can be isolated from the underlying software or hardware layer (EN 301 549 v3.2.1)

Examples: An operating system, device drivers, window systems and software toolkits (DIN EN ISO 9241-161)

Note: A browser can function both as an application and as platform software. (DIN EN ISO 9241-161)

Pointer

Graphical symbol whose position on the screen is changed according to the movement of a pointing device, and whose shape can be adjusted depending on the control element which is situated beneath it (DIN EN ISO 9241-171:2008)

Pointing device

Pointing instrument;

An auxiliary which converts an operational step of the user into a step that is displayed on the screen

Note: Depending on the technology used, both mechanical auxiliary products and parts of the human body (e.g. fingers, arms) can be used as pointing devices. (DIN EN ISO 9241-171:2008)

Quick navigation

Keyboard navigation in which navigation steps are skipped to enable the efficient operation

Real-time event

An event that a) occurs at the same time as it is viewed, and b) is not entirely generated by the content

For example: "Web cast" of a live performance, online auction ([real-time event \(Web Content Accessibility Guidelines \(WCAG\) 2.0\) \(w3.org\)](#))

Role

UI element type for user interfaces;

Characteristic which serves as a known identifier, indicating the type of UI element;

Client applications, especially assistive technology, use the characteristic in order to identify the functions of a control element and to determine how to interact with it

Screen magnifier

Assistive technology for the individualizing of the visual display

Frequent functions are:

- Zoom
- Color adjustment
- Highlighting of the focus indicator, text cursor and mouse pointer
- Reading out of text
- Linearized presentation of text with freely selectable font styles/sizes

Screen reader

Assistive technology which enables users to use software without having to see the visual display (DIN EN ISO 9241-171:2008)

The UI elements are output acoustically by speakers or headphones and on a tactile basis with the use of a Braille display.

The input and control takes place with the keyboard or the Braille display. The inputs are initially processed by the screen reader before being forwarded to the user interface.

Shortcut key

Mnemonic, menu accelerator, accelerator key, shortcut keys

Keys and combinations of keys for initializing a menu option without displaying the corresponding menu with the option or intermediate menus on the screen

For example: Save (ALT + S)

- S = shortcut key – only works when the menu is open and has the focus
- ALT + S = keyboard shortcut – always works (unless the function is temporarily disabled)

Skip link

An internal page link to skip areas of content during the keyboard navigation

Speech recognition software

Assistive technology for the input of text (dictation) or control commands for the running of control elements

An alternative method of input for the mouse or keyboard interface

Standard element

UI elements that are defined by the programming language by default

Status

State;

dynamic characteristic which expresses the characteristics of a UI element which is able to change in response to actions by the user or automated processes

The status does not affect the nature of the UI element, but represents data which is assigned to the component or user interaction capabilities

Examples: focused, selected, pressed, highlighted, operable/disabled, correct/incorrect and open/closed, read-only

Status message

Change in content which is not a change in context, and provides users with information about the success or outcome of an action, the waiting state of an application, the progress of a process, or the presence of errors ([status message - Web Content Accessibility Guidelines \(WCAG\) 2.2 \(w3.org\) \(External Link\)](#))

Support services

Support services include, but are not limited to: Help desks, call centers, technical support, mediation services and training (see also EN 301 549: 12.2.1)

Text cursor

Text indicator;

visual display of the current cursor for the text input (DIN EN ISO 9241-171:2008)

UI

All components of an interactive system (software or hardware) that provide users with information and control elements in order to be able to perform specific work tasks with the interactive system (DIN EN ISO 9241-171: 2008)

UI element

User interface element

User interface element; elementary component of the user interface which is displayed or otherwise presented to the users by the software (DIN EN ISO 9241-171:2008)

User agent

Software which retrieves and displays content for users (EN 301 549 v3.2.1:2021)

User preferences

Individualization, customization;

The modification of the interaction and the presentation of information in order to respond to the individual abilities and requirements of the user (DIN EN ISO 9241-171:2008)

Value

Form elements have a value which is communicated when the form is submitted. In an input field, the value is the entered text. In a selection list, the value is the selected option.

Virtual cursor

The virtual cursor is a mode of the screen reader. It is used, for example, in order to read Web pages in a Web browser (unless they are marked with `role=application`), PDF documents in a PDF reader, or content in hybrid desktop software. Although it is not visible like the mouse cursor, the virtual cursor simulates an insertion point, and offers the same functionality as when reading a text-based document.
